# How the Purity of LACTOGEN is Ensured and Safeguarded

In the production of Lactogen, every possible safeguard and precaution is taken to ensure the maintenance of purity at every stage. Only the purest and richest cows' milk, after special tests, is used in the preparation of Lactogen. Right through the process of manufacture, rigid safeguards are taken to ensure freedom from contamination. The finished product, which is untouched by hand throughout, is packed in specially designed airtight containers as a final safeguard. Thus Lactogen, which in proportion and in physical characteristics so closely resembles breast-milk, is also the safest food that it is possible to obtain.

**"LACTOGEN"**  
*The Better Milk for Babies*

C-2574/38

FREE SAMPLES with detailed descriptive literature will be sent to any member of the Medical Profession, upon request. Lactogen Bureau, Nestle's Milk Products Ltd (Dept Z174) St George's House 6 & 8, Eastcheap, London E.C.3.

# TRADITIONAL LONDON

THE INNER TEMPLE GATE HOUSE,  
FLEET STREET

H BERNARD ROBINSON

*Rebuilt in 1610 it was probably the Council Chamber of the Duchy of Cornwall, which at least as early as 1617 is known to have been located in Fleet Street. It is the oldest surviving house in Fleet Street and the finest specimen of ancient domestic architecture in the City.*

London Hospital Catgut has no less finer traditions behind its development to a leading place in the esteem of Surgeons the world over. It is a product of scientific research, made throughout at the London Hospital under licence of the Ministry of Health.

No underwear is comfortable which in any way irritates the skin—nor is it healthful. DR. DEIMEL UNDERWEAR is soft, soothing and agreeable to the most sensitive skin. The garments are made of a two ply composite thread of vegetable origin woven in a porous manner providing a calm layer of air around the body. A change into DR. DEIMEL UNDERWEAR may be made at any time. It is a change for the better and cannot be made too soon.

Can be washed in boiling water for sterilization without injury.

## A NEW TECHNIQUE FOR THE INFUSION OF BLOOD AND SALINE

The infusing of citrated blood and saline by means of the new Baxter Indirect Blood Transfusion Apparatus, coupled with a Baxter "Vacoliter" of Saline Solution, is the latest contribution on the part of Baxter to Intravenous Therapy.

Over 400 Hospitals in England have standardised on Baxter's Intravenous Solutions in "Vacoliters" and we are glad to present this further evidence of the efforts of the Baxter Laboratories to improve and simplify Hospital methods.

We shall be pleased to send on request further details regarding the Baxter Blood and Saline Infusion Technique and welcome the opportunity to show you how simply and effectively it operates.

# THROMBIN-COAGULANT-MAW DRESSINGS

## FOR THE MAJOR OPERATION OR THE MINOR CUT

Some time ago we announced the production of Thrombin-Coagulant-Maw, a preparation of remarkable efficiency for clotting blood

We now offer a range of Surgical Dressings known as Thrombin-Coagulant-Maw Dressings, to which this preparation has been applied with such regard for the scientific principles concerned, both chemical and physiological, that we venture to suggest a new method of treatment has been found

THE PHYSIOLOGICALLY CORRECT FIRST DRESSING

Whenever a wound is accessible to the application of a Dressing, T C M Dressings will be found of great value in all cases requiring hæmorrhage control. They are very reasonable in price and represent a true economy of your own time and money, whenever hæmorrhage has to be treated

## REDUCED TOXICITY

In anti-bacterial therapy is an important consideration. Abundant clinical evidence has established RUBIAZOL as a highly active and safe remedy for all haemolytic streptococcal infections.

### ADVANTAGES INCLUDE

- The most acute cases respond to a daily dose of 2 grammes (30 grains)
- No clinical manifestations of toxicity noted after two years trial on the Continent
- Is effective in prophylaxis and treatment

# BALANCED NUTRITION

## IN A 3-CEREAL FOOD

Farex is a fully cooked cereal powder blended from wheat, oatmeal and maize, and vitalised with yeast, basic phosphates, iron and the protective vitamins. Its comprehensive formula makes Farex eminently suitable as a light but sustaining diet during illness, in gastric disorders and after dental extraction.

For young children and adolescents, its vitamins and minerals promote proper formation of growing tissues. As the basis of a weaning diet Farex supplies all-round nutritional factors in the most easily assimilable form.

Farex is appreciated by busy doctors as well as their patients. Instantly ready to serve with any flavouring and fluid desired (e.g. as a *tonic breakfast*). Farex can be eaten even in haste without taking digestion, efficiently replacing a full meal when time is pressing.

In cartons 1/- and 1/6 (double quantity)

# "ALOCOL"

Colloidal Hydroxide of Aluminum

## Improved Antacid Therapy

**S**ODIUM BICARBONATE bismuth salts and other time-honoured antacids having each proved to possess individual disadvantages an agent such as Alocol which combines the best therapeutic features of these with intrinsic merits of its own must be of interest to the physician

Alocol is a powerful antacid agent which forms with the stomach contents a colloidal jelly with the power of adsorbing free hydrochloric acid thus fixing it and eliminating it from the system. It has a remarkable soothing effect on the inflamed or irritated gastric mucosa and is therefore rapidly effective in relieving pain. Being non absorbable Alocol is free from any risk of alkalosis.

Alocol can be prescribed with confidence in all cases where alkaline therapy is indicated. Issued in tablet and powder form.

Complete clinical history of Alocol with convincing clinical reports and supplementary material sent free to physicians on request.

# ALASIL

## Safe Salicylate Therapy

**T**HE popularity of acetyl salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non narcotic analgesics available. Too often however its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

Alasil provides the beneficial therapeutic effects of pure acetyl salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl salicylate—the least irritating salicylate compound—with Alocol a potent gastric sedative and antacid.

Since Alasil is better tolerated than acetyl salicylic acid its use can be pushed or prolonged to a much greater extent than the latter.

Alasil is therefore an analgesic, antipyretic and anti rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

OVER 60 YEARS' REPUTATION

INDICATIONS FOR 'SANATOGEN'

No 2

# Disease-emaciation

"EVERY medical practitioner knows how difficult it is to nourish a patient suffering from disease-emaciation. Do we not all recognise the fact that the starving tissues are fed, not by the food swallowed by the patient, but by the amount of nutrient matter absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood, the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. Judging from clinical results, 'Sanatogen' appears in many cases to possess some power of ready absorbability, without which the richest foodstuff represents simply so much foreign matter in the stomach and intestines. My own experience of 'Sanatogen' is that it stays the diarrhoea—ten or twelve motions a day are thereby reduced to one or two, it stops vomiting, and it improves general conditions and causes the patient to put on flesh."

"NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS"  
(*Medical Press and Circular*)

"THIS condition, which results from imperfect digestive or absorptive power, or which may follow stomatitis, pyloric stenosis, deformity of the tongue or palate, tuberculosis or syphilis, is most frequently associated with improper feeding. Fats in such cases are not well tolerated, but the contrary is true with respect to proteids. The use of 'Sanatogen', in these cases, proved so satisfactory that we have been encouraged to try it in other cases of infantile atrophy, and have had almost equally pleasing results in a number of patients suffering from this condition. It is quite apparent that 'Sanatogen' has considerable power in influencing nutrition."

"INFANTILE ATROPHY"  
(*Practitioner*)

"I HAVE before me the records of forty cases fed with 'Sanatogen'. They show, what was obvious to myself and the nurses when watching the cases, that these patients wasted less during the acute stage, and picked up more rapidly during the convalescent stage, than patients who did not have 'Sanatogen'. This fact, indeed, was soon recognised by the ward sister, without my having in any way drawn her attention to it. . . I am firmly convinced that it is a most valuable food for the typhoid patient."

"THE TREATMENT OF TYPHOID FEVER"

# AN IMPORTANT ADAPTATION OF MEDICAL TECHNIQUE TO *Menstrual Hygiene*

## TAMPAX

### SANITARY PROTECTION WORN INTERNALLY

A great advance in the hygiene and comfort of sanitary protection has been achieved by the application of medical technique. The tampon used in vaginal therapy has been adapted by a physician for the internal absorption of the menstrual fluid.

Tampax is composed of highly absorbent long-fibred surgical cotton, which has been sterilised and compressed. Each tampon has an absorption capacity of 1 to 1½ ounces. As it absorbs the menstrual fluids, the tampon opens gently to a soft mass, comfortably adapting itself to the size and form of the vaginal walls. Protection is complete, while all chafing is eliminated. Contamination from the urethra is minimized, and infections of rectal origin are likewise avoided.

A patented sealed applicator enables the user to insert Tampax in the proper position without contact with the hands. It can be removed in an instant by means of a cord sewn through the cotton by an exclusive stitching process which makes disintegration impossible.

Dispensing with the sanitary towel, Tampax ensures the maximum degree of cleanliness, comfort and freedom during the menstrual period. Physicians may recommend it to the vast majority of their women patients in the fullest confidence.

We will be glad to send to doctors a full size package of Tampax, together with a folder giving more complete details on request to Tampax Ltd 10, Bolton Street, London, W 1.

# MILTON AS A DOUCHE

Patients often ask for advice on a suitable antiseptic. In the many cases where a douche is indicated, Milton is particularly suitable.

- 1 It is alkaline with a pH of about 10, due to sodium carbonate and not to caustic soda. On dilution it forms a mildly alkaline solution which corrects any acidity, but does not harm mucous membranes.
- 2 Even at considerable dilutions, it is still a hypertonic solution.
- 3 It is miscible with mucus and pus and dissolves semi-solid proteid matter, thus acting as a cleansing agent.
- 4 As will be readily appreciated from its content of 1 per cent of hypochlorite, it has a powerful germicidal action on any micro-organisms likely to be found in the vagina or uterus. For *B. coli*, for example, it has a R.W. Coefficient of 2.12.
- 5 It is a deodorant with immediate action, destroying the organic gases by oxidation.

Owing to its reasonable price—Milton is sold by all chemists from 6d per bottle upwards—it can be recommended even when expense is a main consideration.

A copy of the Pease Laboratories' Report on Milton, some notes on the value of Milton in Gynaecology, and a generous professional sample bottle of Milton will be sent to any medical practitioner.

## THE CLINICAL ASPECTS OF THE TRANSMISSION OF THE EFFECTS OF NERVOUS IMPULSES BY ACETYLCHOLINE\*

FRANCIS R FRASER M.D. F.R.C.P.

*Professor of Medicine University of London Director of the Department of Medicine  
British Postgraduate Medical School*

### LECTURE I

#### Physiology of Acetylcholine

The brilliant researches by Loewi and Dale and their co-workers since 1921 have built up step by step a firm structure upon which rests the belief that acetylcholine transmits the effects of nervous impulses from the nerve endings to the organs throughout a large part of the body. It is not necessary for the purpose of these lectures to review this evidence for a number of able exhaustive and critical accounts have been published recently (Loewi 1933, Alles 1934, Dale 1934, 1935, 1937, Bacq 1935, Gaddum 1936, Brown 1937 and Cannon and Rosenbluth 1937) but the main conclusions will be briefly recounted.

When a new principle is established that clarifies our understanding of the processes by which the body normally functions and indicates an essential link in the chain of events that lead to the actions of our organs in health clinicians should consider whether this new principle may not throw light on some abnormality of function that is observed in disease for it some deviation from the normal process should occur it may be expected to produce abnormalities of function with accompanying signs or symptoms. Furthermore when in this instance the new physiological principle involves the presence of a chemical substance which has specific and striking effects when administered to the animal body the investigation of its action on human beings in health and disease is clearly indicated in an endeavour to utilize the newly discovered pharmacological effects for cure or alleviation of ill health.

FIG 1

I propose in this first lecture to describe briefly what is now the accepted place of acetylcholine in the normal functioning of the body and the conditions that modify its actions to describe the effects of administering it to

animals under experimental conditions the effects in more detail of administering it to normal human beings and the attempts that have been made to use it for therapeutic purposes.

The transmission by acetylcholine occurs in its simplest form between the nerve endings of the parasympathetic or cranio-sacral portion of the autonomic nervous system and the effector organs supplied by it and Fig 1 shows diagrammatically what is believed to occur. On the arrival of the impulse at the nerve endings acetylcholine is formed and transmits the effect of the nerve impulse to the cell of the effector organ producing in it its physiological action whether that be stimulation or inhibition. Since the effect of such a nerve impulse is short lived it is unlikely that acetylcholine is there previous to the arrival of the impulse and it must be rapidly removed or destroyed following the impulse.

#### ORIGIN OF ACETYLCHOLINE

How the acetylcholine is produced is still uncertain. It may be set free from a preformed compound or it may be synthesized by the arrival of the impulse. Brown (1937) has summarized what is known of its storage and liberation and Mann, Tennenbaum and Quastel (1938) have recently brought forward evidence pointing to the presence in the brains of rats of a precursor which is synthesized during tissue respiration in the presence of glucose which is itself inactive and from which acetylcholine can be set free by denaturing tissue proteins. Their work is suggestive but in the meantime the origin of the acetylcholine set free on the arrival of a nerve impulse must be regarded as unknown.

#### DESTRUCTION BY ESTERASE

The extraordinary evanescence of the action of acetylcholine was noted by Dale (1914) and he suggested that it was rapidly hydrolysed by an esterase. This has been confirmed by a number of workers (Loewi 1921, 1922, Loewi and Navratil 1926, Galehr and Plattner 1927) and the action of the esterase has been carefully studied by Matthes (1930). Its specificity for choline esters was demonstrated by Stedman, Stedman and Easson (1932) and Plattner and Hintner (1930) determined its distribution in the organs and tissues of the body. The choline esterase activity of sera from normal man and from patients has been estimated by Lucas, Hall and Ettinger (1935), Verebely (1926) and McGeorge (1937) but owing to technical difficulties it has not been possible to assess the esterase activity at parasympathetic endings though

\*The Croonian Lectures delivered before the Royal College of Physicians of London on May 24, 26 and 28, 1938.

Brucke (1937) has shown that sympathetic ganglia contain considerable amounts of choline esterase. It is therefore probable that, following the arrival of the impulse at the nerve endings, the acetylcholine is produced, transmits the effect of the impulse, and is almost immediately destroyed by the choline esterase present locally in the tissue.

#### ACTION OF PHYSOSTIGMINE

Loewi and his co-workers observed that the rapid hydrolysis of acetylcholine was inhibited by physostigmine (eserine). This inhibition has been studied by Engelhart and Loewi (1930) and by Matthes (1930), who showed that physostigmine could inhibit the action of choline esterase in as low a concentration as one part in 30 millions and that the action is reversible, the esterase activity being restored when the physostigmine is removed by dialysis. Jones and Todd (1935) found that the subcutaneous injection of physostigmine in man depressed the esterase activity of human serum. This action of physostigmine has been of great importance in proving the presence of acetylcholine following stimulation of nerves, for by preventing the rapid destruction of the ester the addition of physostigmine to perfusion fluids has enabled acetylcholine to be identified in the perfusion fluid following nerve stimulation. Further, the addition of physostigmine causes an intensification and prolongation of the effects of acetylcholine, an action which is specific for choline esters and is utilized in the recognition and identification of choline esters or of acetylcholine itself. This action of physostigmine throws light on its established therapeutic uses as a parasympathetic stimulator and is shared by a substance of similar composition, prostigmin, a synthetic compound that has already found an important place in therapeutics.

#### ACTION OF ATROPINE

The effects following injection of acetylcholine into the circulation had an important role in the development of the knowledge of the action of that substance as transmitter of the effects of nervous impulses, and it was noted by Dale (1914) that many of the pharmacological results could be prevented by atropine. Many of the effects of nerve stimulation where acetylcholine is believed to be the transmitter are similarly prevented by atropine, and Loewi and Navratil (1924) showed that even where atropine prevents these effects, as in the frog's heart, it does not prevent the appearance of acetylcholine. Atropine therefore inhibits the effect of acetylcholine on the cell of the

FIG 2

effector organ but not the production of the acetylcholine on the arrival of the impulse at the nerve endings. The actions of physostigmine and of atropine on acetylcholine transmission are shown diagrammatically in Figs 2 and 3.

At certain sites where acetylcholine is believed to be the transmitter atropine, while preventing the effects of injected acetylcholine, does not prevent the effects of nerve stimulation. This lack of uniformity in atropine inhibition has created difficulties in the acceptance of acetylcholine as the transmitter at these places where atropine

fails to inhibit the effects of nerve stimulation. Dale and Gaddum (1930) pointed out that the potentiation by physostigmine of the effect of nerve impulses in these instances undoubtedly indicated transmission by a choline ester, and suggested that "in such cases the nerve impulses liberate acetylcholine so close to the reactive structures that atropine cannot intervene, whereas it can prevent its access to them when it is artificially supplied from without."

At certain other sites of acetylcholine transmission atropine not only fails to prevent the effects of nerve stimulation but fails to inhibit the action of injected acetylcholine. At these situations the association between the

FIG 3

nerve endings and the effector cells may be still more intimate.

The action of atropine in relation to acetylcholine transmission accounts for many of its pharmacological actions and of its therapeutic uses, which are based in most instances on its capacity to inhibit parasympathetic effects.

#### DISTRIBUTION OF CHOLINERGIC NERVES

The nerves whose effects are transmitted by acetylcholine do not belong to any anatomical group, and Dale (1933) has suggested the term 'cholinergic' for their designation, the term 'adrenergic' being applied to the nerves whose effects are transmitted by adrenaline or some other chemical substance closely allied to adrenaline.

The cholinergic nerves may be subdivided into those whose action resembles the effects of the administration of muscarine, and those whose action resembles the effects of nicotine. In most instances the muscarine-like transmissions can be prevented by atropine, while in no instance is the nicotine-like transmission prevented by atropine, but the important distinctions between the two types of transmission are found in the latent period, duration and localization of response, and potentiation by physostigmine. In the muscarine-like transmission the latent period is longer, the duration of the effect is longer, the effect is less strictly localized, and physostigmine produces constantly an increase in the magnitude and duration of the response.

As the result of experiments on mammals, the cholinergic nerves with a muscarine type of transmission are found to include the postganglionic fibres of the parasympathetic or cranio-sacral autonomic system. The following actions belong to this group:

- (a) Constriction of the pupil by oculomotor fibres
- (b) Salivation by the chorda tympani
- (c) Cardiac inhibition by the vagus
- (d) Bronchial constriction by the vagus
- (e) Increased tone and contraction of oesophagus, stomach, small intestine, colon, and rectum by the vagus and the sacral outflow
- (f) Contraction of the bladder by the sacral outflow and pelvic nerves
- (g) Slight contraction of the uterus by the sacral outflow and pelvic nerves.

(n) Vasodilatation through the chorda tympani and (in some animals) in the distribution of the vagus

(i) Vasodilatation in the external genital organ by its sacral outflow and nervi erigentes

Of these constriction of the pupil stimulation of the salivary glands cardiac inhibition and bronchial constriction are inhibited by atropine. There is still doubt as to the effect of atropine on the nervous impulses to the stomach but the action on the intestines bladder and uterus and the vasodilator effects of the chorda tympani and nervi erigentes are not inhibited by atropine.

Other cholinergic nerves with a muscarine type of transmission are

(j) The post ganglionic sympathetic fibres to the sweat glands

(k) Sympathetic vasodilators to the muscles

In both of these the effects of nerve stimulation are abolished by atropine.

(l) The antidromic vasodilator impulses conveyed by sensory nerves to the cutaneous vessels are cholinergic but are not inhibited by atropine.

In view of the vasodilator effect of choline esters when administered by injection producing generalized vascular dilatation involving the vessels of the skin muscles kidneys lungs liver and brain it is probable as Brown (1937) suggests that vasodilators throughout the body are cholinergic.

The cholinergic nerves with nicotine like transmission are

(i) All preganglionic fibres acetylcholine acting as the transmitter at ganglionic synapses both in the parasympathetic and in the sympathetic autonomic system

(ii) The motor nerves to the skeletal muscles acetylcholine being the transmitter at the neuromuscular junction

For technical reasons it has not been possible to demonstrate the production of acetylcholine at the ganglionic synapses of the parasympathetic system where the ganglia are situated close to the effector organ and the post ganglionic fibres are short but there is evidence from the regeneration experiments of Langley and Anderson (1904) indicating that transmission at these ganglia is the same as at the sympathetic ganglia. Embryologically the medulla of the adrenal body is analogous to sympathetic ganglia and stimulation of the sympathetic fibres to the adrenal body with the resulting secretion of adrenaline has been shown to be accompanied by the production of acetylcholine.

(iii) The nerves to the adrenal medulla are thus similar to preganglionic sympathetic fibres and are cholinergic and of the nicotine type.

All neurones leaving the central nervous system are thus seen to be cholinergic and the only effector peripheral nerves that are not cholinergic are the post-ganglionic fibres of the sympathetic system. But the post ganglionic sympathetic fibres to the sweat glands and the post ganglionic sympathetic vasodilator fibres to muscles are cholinergic and in addition the antidromic vasodilator impulses through sensory nerves to the cutaneous vessels of the limbs are cholinergic.

The diagram published by Dale (1934) illustrates concisely this distribution of cholinergic fibres.

## Pharmacology of Acetylcholine

The effects of acetylcholine when administered to animals under experimental conditions afforded valuable evidence that suggested the possibility of this substance acting as a chemical transmitter and strongly supported the part played by it in physiological processes. Hunt and Taveau (1906) observed its prompt depressor effects. Dale (1914) studied its actions in cats anaesthetized or with the brain destroyed and found that while very small doses (0.0001 mg) by intravenous injection produced a fall of blood pressure through vasodilatation larger doses (0.01 mg) caused a slowing of the heart followed by poisoning. It stimulated contraction of the unstriated muscle of the digestive tract caused the bladder to contract constricted the bronchioles produced miosis and increased the flow of tears saliva and pancreatic juice. It also produced sweating on the pads of the cats' foot. All these actions could be prevented or diminished by atropine.

### MUSCARINE LIKE AND NICOTINE LIKE ACTIONS

Following the administration of atropine larger doses of acetylcholine produced a pressor effect. Dale stressed this dual action pointing out that the effects of smaller doses which could be inhibited by atropine resembled those of muscarine and that the effects of larger doses following the inhibition by atropine of these muscarine like actions resembled those of nicotine. With the exception of the peripheral vasodilatation and the sweating the muscarine like effects imitated closely those produced by stimulation of the cranio sacral or parasympathetic division of the autonomic nervous system.

Dale tried administration by subcutaneous injection. He found that a dose of 10 mg had no effect but that following 20 mg in a smaller cat weighing 2 kg slowing of the heart an increased flow of tears and of saliva sweating retching borborygmi and the exudation of slime from the anus laboured respiration erection of the penis and the passage of urine occurred.

Further studies of the pharmacological effects of acetylcholine have confirmed these generalizations and its actions in mammals under experimental conditions include constriction of the pupil (Lipschutz and Schilt 1931) and under certain conditions a fall in intra ocular pressure (Colle, Duke Elder and Duke Elder 1931) lacrimation salivation constriction of bronchioles increased bronchial secretion (Schilt 1932) increased depth and frequency of respirations (Gaddum 1936) inhibition of the heart, increased tone and peristalsis of oesophagus stomach small intestine and colon secretion of gastric juice (Gebhardt and Klein 1933) contraction of the gall bladder and relaxation of Oddi's sphincter (Kitakoji 1931) increased secretion of pancreatic juice contraction of the capsule of the spleen (Saad 1935) contraction of the urinary bladder feeble contraction of the uterus (Murakami 1931) vasodilatation in organs supplied by the parasympathetic nervous system generalized vasodilatation of the cutaneous arterioles including those of the limbs and the surface of the brain (Wolff 1929) and sweating. All these effects are inhibited by atropine. With larger doses and unaffected by atropine it has a pressor and cardio-accelerator effect through stimulation of the ganglia of the sympathetic nervous system and the adrenal glands and it stimulates contraction of striped voluntary muscle fibres.

The effects following subcutaneous injection are uncertain and variable and those following intravenous or

intra-arterial injection are remarkably evanescent owing to the rapid hydrolysis of acetylcholine by the choline esterase present in the blood and in the tissues. Physostigmine, by inhibiting this destruction by the esterase, can greatly increase and prolong all these effects.

### Actions of Acetylcholine in Man

In 1916, at the suggestion of Sir Henry Dale and with the assistance of R. M. Wilson, I began studies on the action of acetylcholine chloride in man, but we were unable to complete them at that time owing to the requirements of military service. We found, however, that when given by subcutaneous injection there were no apparent effects, and that even when introduced intravenously no effect was obtained if blood from the vein was allowed to flow back into the syringe. These results were probably due to the rapid destruction of the acetylcholine by choline esterase.

Villaret and Justin-Besançon (1928) were the first to report the action of acetylcholine in man. They found that it had no action when given orally, and considered that it was dangerous when given intravenously. On subcutaneous injection in doses of 0.01 to 0.05 gramme no subjective phenomena occurred, but they were able to observe a dilatation of the retinal arteries. Larger doses—0.2 to 0.4 gramme—produced a sensation of warmth and sometimes a slight and transient fall in blood pressure and slight bradycardia. As noted by Hunt and Taveau (1906) and by Dale (1914) in animals, so it was noted by Villaret and Justin-Besançon in man that there was considerable variation in the intensity of effects in different subjects and at different times in the same subject. In view of the pronounced action of small intravenous doses in animals and the relatively large doses employed by Villaret, it is probable that only a trifling amount escaped destruction at the site of injection or in the blood stream and reached the organs of the body.

In 1932 Ellis and Weiss reported the effects in normal subjects of the administration of a 2 per cent solution by intravenous and intra-arterial infusion. When given intravenously at the rate of 0.02 to 0.14 gramme per minute, flushing of the head and upper part of the body, throbbing in the head, palpitation, sweating, salivation, lacrimation, substernal constriction, nausea, and vomiting were observed. They found practically no effect on the heart rate, and only three out of thirteen subjects showed an appreciable fall in blood pressure. The intra-arterial infusion in four subjects produced flushing, sweating, heat, and increased arterial pulsation distal to the site of injection. In the same year Loeper, Lemaire, and Dany (1932) reported that they obtained contractions of the gall-bladder in dogs, and that, following the intravenous injection of 0.05 to 0.01 gramme in six human subjects, there was an increased flow of bile into the duodenum.

In 1933 E. A. Carmichael and I recorded the results of intravenous injection of acetylcholine in forty-six subjects. Doses of 0.01 to 0.03 gramme produced cardio-inhibitory effects, which appeared five to ten seconds after the injection and lasted for a few seconds only. The slowing of the heart was followed by a rise of rate above the original level: the systolic and the diastolic blood-pressure fell during the phase of slow heart rate, but returned to their original level or a little higher during the phase of rapid heart rate. A feeling of warmth throughout the body, flushing of the face, neck, and upper thorax, coughing, and a sense of obstruction to respiration occurred, but they varied in incidence and intensity in different subjects.

All these effects could be abolished by atropine and be intensified and prolonged by physostigmine. By intra-arterial injection we obtained flushing of the skin twenty seconds later in the area corresponding to the territory supplied by the artery, but we could observe no effect from subcutaneous or intramuscular injection in doses up to 0.5 gramme.

From these results and those obtained by Ellis and Weiss (1932) by continued infusion it appears that the muscarine-like effects noted in animals under experimental conditions can be obtained in man. There was, however, no evidence of the nicotine-like actions, and, although carefully looked for, no evidence of constriction of the pupil with the doses employed.

Of interest in relation to the nicotine-like effects on voluntary muscle in animals is the observation of Lanari (1936) that when 0.04 gramme of acetylcholine was given by intra-arterial injection there was no apparent effect on the muscles in normal subjects, but that slight contractions were seen in the muscles of the injected limb in cases of nerve section, strong contractions in pyramidal rigidity, moderate contractions in pyramidal lesions with flaccidity, and slight twitches only in extrapyramidal lesions and myopathies. He later (1937) described muscular contractions in cases of myotonia, with the same method of administration.

There seems to be no doubt that effects can be obtained by subcutaneous or intramuscular injection, but these methods of administration are unreliable. Villaret, Schiff-Wertheimer, and Justin-Besançon (1928) reported that they obtained in eleven of twenty-five subjects undoubted dilatation of the retinal arteries four to six minutes after the subcutaneous injection of 0.05 to 0.15 gramme. The effect lasted for six to nine minutes. Lemaire and Bioy (1934), following the subcutaneous injection of 0.2 gramme, observed a rise of pressure in the cerebrospinal fluid, due possibly to dilatation of the cerebral vessels. The rise lasted for fifteen to twenty minutes, but often failed to appear. This observation is of interest in connexion with the results obtained by Wolff (1929) in cats. He gave 0.02 to 0.2 mg intravenously to four cats prepared by trephining so that the cerebral vessels could be observed through a window. Accompanying a fall in systemic blood pressure, an increase in the diameter of the pial vessels was observed and a rise in the pressure of the cerebrospinal fluid which he considered was due to the increased size of the cerebral vessels. Merklen, Warter, and Kabaker (1932) studied the effect on gastric secretion of the subcutaneous injection of 0.2 gramme, and considered that a rise in hydrochloric acid and total acidity resulted in subjects with normal or low acidity, but that there was a fall in subjects with high acidity. Faroy and Deron (1931), using similar doses by intramuscular injection, found no rise in the hydrochloric acid content in normal subjects, but in some cases a fall.

### Acetylcholine in Therapeutics

In spite of its uncertainty when injected subcutaneously or intramuscularly, acetylcholine administered by these routes has been extensively employed for the purpose of obtaining either parasympathetic or vasodilator effects in patients. With the possible exception of its use by subconjunctival injection in spasm or embolism of the retinal arteries and in chronic glaucoma, the results have been unsatisfactory, either no effects being produced or there being so much uncertainty that other methods of obtaining them are preferable. It has usually been administered as

the chloride or bromide of acetylcholine dissolved immediately before use or stabilized in acid solution as it decomposes rapidly in alkaline solution

#### GASTRO-INTESTINAL

Abel (1933) gave 0.1 gramme by intramuscular injection hourly for six hours to fifty patients after laparotomy, starting thirty-six hours after operation until flatus or faeces were passed and concluded that such treatment appears to be almost specific in curing paralytic ileus. Heritage (1933) reported good results in similar conditions and Heitz (1929) extremely good results in lead colic. Gebhardt and Klein (1933) gave 0.1 gramme by subcutaneous injection to fifty patients with subacidity of gastric secretion or anacidity in single doses or in series of small daily doses and found an increase in acidity in a small number. He concluded that it had no true therapeutic value.

#### VASODILATOR

Numerous authors have found that in hypertension acetylcholine might cause a fall of blood pressure in doses of 0.1 to 0.2 gramme by subcutaneous or intramuscular injection but that the effect was temporary and that it had no therapeutic value in this condition. In vasospastic conditions arterial disease with pain or trophic lesions such as Raynaud's syndrome, intermittent claudication and trophic ulcers and in varicose ulcers several authors have reported that it caused a diminution of pain and early healing but their papers are not convincing. Siclounoff (1934) thought its employment deserved consideration in cerebral thrombosis to hasten recovery and de Gennes (1932), Pagniez, Plichet and Decourt (1932), Louyot (1933) and McLaughlin (1933) were of the opinion that daily doses of 0.1 to 0.3 gramme by subcutaneous injection in epileptics lessened the severity or number of attacks. Janet, Vallery Radot, and Huguet (1932) reported great improvement in two cases of acrodynia following five or six injections of 0.05 gramme at intervals of up to two days. Guns and Coene (1929) and Angelescu (1932) used it in ozaena irrigating the nasal passages with a 5 or 10 per cent solution after rendering the passages acid by previous washing with a 1 to 2 per cent solution of lactic acid; they regarded the results as hopeful.

#### IN OPHTHALMOLOGY

A more promising field for acetylcholine in therapeutics is in the treatment of congestive glaucoma and in spastic or obstructive conditions of the retinal vessels. If given by subconjunctival injection a local effect—miosis and lowering of intra-ocular tension—is obtained in chronic glaucoma and Villaret and his co-workers have stressed the vasodilatation of the retinal vessels that follows subcutaneous or intramuscular injection. Velhagen (1932) showed in cats that acetylcholine is present in the visual tract and the retina and that in glaucoma it constricts the pupil, dilates the retinal vessels, and lowers the tension. Gallois (1930) reported that following six injections of 0.1 gramme in a case of chronic glaucoma progressing unfavourably there was an improvement in the field of vision and a fall in tension. In this country Evans and Evans (1934) treated six cases of congestive glaucoma by means of subconjunctival and intramuscular injections and recorded a fall of intra-ocular tension without change in the systemic blood pressure. The chief defect in this method of treatment they point out is the evanescence of the action. Dejean (1932) recommended the use of 0.1 gramme by subcutaneous injection in ophthalmic migraine and de Saint Martin (1931) con-

sidered that similar doses gave relief in various spastic conditions of the retinal arteries. Villard, Dejean and Temple (1932) obtained a prompt return of vision in one of three cases of thrombosis of the central artery of the retina. Hartmann (1933) gave repeated intramuscular injections of 0.1 gramme in various arterial lesions with visual defects obtaining favourable results and Orr and Yeung (1935) by subconjunctival injections obtained a rapid return of vision in a case of embolism of the central artery of the retina and the embolus was observed to move towards the periphery. Duggan (1937a) treated two cases of acute retrobulbar neuritis with repeated doses of 0.1 gramme intramuscularly and considered that the vision returned more rapidly than in eight similar cases treated with amyl nitrite or intravenous injections of sodium nitrite. Hartmann (1933) believed acetylcholine to be the best therapeutic agent in tobacco amblyopia when given by the intramuscular route. Orr (1936) reported good results from the same method and Cragg (1936) concluded that it hastened recovery but Duggan (1937b) who used intravenous injections found it of doubtful value.

These results of the administration of acetylcholine to man by intra-arterial, intravenous, intramuscular, or subcutaneous injection whether in normal subjects or in patients are disappointing from the therapeutic point of view. When it is given by intravenous injection the effects are too brief when given by intramuscular or subcutaneous injection too uncertain. They are however of importance as indicating the nature of the actions that can be obtained and pointing to possible therapeutic uses of the principle of acetylcholine transmission if more stable substances with the same or similar actions should be available. A number of other esters of choline and its derivatives were studied by Hunt and Taveau and by Dale and since the publication of their researches many more have been prepared and tested. Of these only two have come into general use for therapeutic purposes—carbaminoyl-choline and acetyl  $\beta$  methyl choline—and their actions and therapeutic uses will be discussed in the next lecture.

In the Chemistry Section at the Cambridge Meeting of the British Association, August 17-28, the president, Professor C. S. Gibson, will review the recent advances that have been made, chiefly by himself and his co-workers, in the chemistry of gold. This opening address will be followed by a discussion on recent advances in the organic chemistry of the metals with special reference to the noble metals. A discussion on modern methods of chemical analysis, including physical and microchemical methods, will be opened by Dr. J. J. Fox, Chief Government Chemist and Professor W. L. Bragg will open a discussion on "Chrys". The fourth symposium, entitled "Repercussions of Synthetic Organic Chemistry on Biology and Medicine," which has an added interest in view of the exceptional circumstance that the Physiological Section will not meet this year, is being arranged by Professors E. C. Dodds and J. W. Cook. Recent work on the production of new compounds having the biological action of the sex hormones will be described by Professor Dodds and Professor L. Ruzicka (Zurich), and Dr. A. S. Parkes will deal with some of their interesting biological interrelationships. The second half of the programme will be occupied with descriptions of synthetic compounds which are able to induce cancer (Professor J. W. Cook) or new compounds having the physiological action of the life maintenance hormone of the adrenal cortex (Professor T. Reichstein Zurich) and of the synthesis of vitamin B<sub>1</sub> and analogous compounds (Dr. A. R. Todd). Specimens and apparatus relating to these discussions will be on exhibition throughout the meeting. By invitation of Sir William Pope a visit will be made to the University Chemical Laboratories and Sir F. Gowland Hopkins has invited the section to visit the departments of biochemistry and biology, and the Moltano Institute.

## SURGICAL TREATMENT OF DISSEMINATED SCLEROSIS BY SYMPATHECTOMY AND GANGLIONECTOMY

### TECHNIQUE BY THE ANTERIOR APPROACH

BY

C. F. KOCH, M.D.,

(From the Surgical Division of the City Hospital of Middelburg)

AND

EUGENE DE SAVITSCH, A.B., M.D.,

C.R.B. Fellow and Associate Lecturer at Institut Bunge, Antwerp

Nothing is more discouraging to the neurologist than the treatment of disseminated sclerosis. The task is made difficult on account of ignorance of the true aetiology of the disease. The correct evaluation of any therapeutic measure is complicated by the irregularity of the symptoms of the disease, with its frequent spontaneous remissions and uncertainty of objective findings. Among the various theories of the aetiology of disseminated sclerosis the vascular hypothesis appears to be the most logical. Putnam (1933, 1931-6, 1937), in his admirable studies, has shown that the histological characteristics of the disease may be closely imitated experimentally by a number of different procedures, all of which have in common an interference with the blood supply of the affected area. These facts, according to this author, give a new importance to the vascular abnormalities which have long been recognized as a characteristic of sclerotic plaques. Putnam further states that if the specific lesion is produced by a simple mechanical interference with the blood supply it is superfluous to postulate a specific demyelinating organism, virus, or toxin to account for such lesions, and that the ultimate aetiological factor should probably be sought in a local vascular abnormality.

### The Vascular Hypothesis

Our procedure is based on the assumption that the hypothesis of Putnam is probably correct. In this we are in agreement with Wetherell (1934, 1935) and Royle (1933), who were able to show the practical application of this theory. We consider that the pathological changes in disseminated sclerosis are attributable to an ischaemic phenomenon resulting possibly from a spasm of the blood vessel supplying the parenchyma of the brain and spinal cord. Our aim, therefore, is to institute a procedure which would tend to lessen the alleged vascular contraction, thus allowing a better blood supply to the involved areas. There is but little doubt that this procedure can in no way remedy the complete damage to the nerve cells and their axons, but it is quite conceivable that the improved vascularization may re-establish some of the functions of partially damaged tissue. That this is possible is best demonstrated by the course of the disease itself. Frequent remissions and sometimes total disappearance of symptoms lead us to believe that in many cases the destruction of the nerve cells is in no sense final, and that when they are placed in more advantageous conditions their function may be regained.

The theoretical aspects of this procedure may be summarized as follows. Vascularization of the brain and the spinal cord depends entirely on the carotids and vertebral arteries. These are innervated by the sympathetic nervous

system through the stellate ganglion and the vertebral nerve. Fig 1 shows in a schematic way the structural relations concerned. As may be seen should a vascular spasm be present it would find its responsible nervous factor in either the stellate ganglion or the vertebral nerve or in both.

FIG 1—Stellate ganglion and vertebral nerve in their relation to the carotid and vertebral arteries (schematic figure).

### Operative Procedure

The extirpation of the upper thoracic and lumbar sympathetic ganglion and trunks by the dorsal approach was carried out successfully by Adson and Brown (1929) in the treatment of Raynaud's disease. The sympathetic ganglionectomy by the anterior approach by the same authors failed to give the desired results. On the other hand Griman (Rieder 1930) and French (Leriche see Cadenat 1933) investigators successfully used the latero anterior route. The dorsal approach necessitates extensive dissection as well as actual costo-transversectomy which is likely to be accompanied by a considerable shock to the patient as in most of the bone operations. The approach of Leriche and Rieder though definitely less traumatizing has the disadvantage of limiting the visibility of the operative field. The technique which we propose is an attempt to eliminate the drawbacks of the earlier trials. Our experience is based on some twenty six operations, most of them in cases of advanced disseminated sclerosis.

### PRE-OPERATIVE ROUTINE

The pre-operative preparation of the patient is essentially the same as in any other surgical procedure. A soap and water enema and a mild sedative of the barbiturate group on the eve of the operation ensure a restful night to the patient. For pre-operative medication a dilaudin-atropine combination gives

excellent results. We feel that avertin by rectum in doses of 70 to 100 mg per kilo of body weight depending on the condition and age of the patient is the anaesthetic of choice. It has the advantage of permitting the anaesthesia to be induced while the patient is still in his room and its lasting effect helps greatly in alleviating post-operative apprehension. Avertin alone is practically never sufficient. It has to be supplemented by local infiltration of 1 to 2 per cent of novocain solution with 16 drops of 1 in 1000 solution of epinephrine per 100 ccm of novocain. In certain cases a few whiffs of ether have to be given in the terminal stages. It is well to have on hand a positive pressure anaesthesia apparatus as occasionally the pleura may be punctured during the course of the operation.

An ordinary thyroidectomy set may suffice but a few specially designed instruments as illustrated in Fig 2 are of

FIG 2—Special instruments. A Depressor B Retractor C Aneurysm needle

considerable help. The depressor A has the advantage of a long handle and curved spoon-like spatula which allow the retraction of the moving dome of the pleura during deeper dissection. For retraction of larger vessels the retractor B ensures a considerable amount of visibility with comparatively great safety. A small aneurysm needle (C) for ligation of smaller vessels is optional.

Careful haemostasis and exact knowledge of the anatomical relations of this region are indispensable in this procedure. Even the slightest haemorrhage obscures the operative field causing a very prolonged and distressing delay. In cases of doubt as to the nature of the structure it is always best to ligate it this precaution saving a great deal of time in the long run. The anatomy of the region though fairly uniform is none the less subject to numerous modifications. The variable calibre and the relative positions of the blood vessels are particularly annoying. The vertebral nerve is a great offender. Its position in reference to the vertebral vessels classically (Hovelacque *et al* 1937) is said to be posterior to the vertebral arteries. In some of our cases the relationship was just the reverse. We emphasize this point in order to place the operator on guard against the unexpected possibility.

### SOME DETAILS OF TECHNIQUE

After induction of the avertin anaesthesia the patient is placed in a semi-reclining position with the neck hyperextended and the head turned away from the side on which the operation is to be performed. It is essential to see that the patient is so securely fixed as not to permit any change of position during the operation. After the infiltration of the skin with local anaesthetic a semilunar incision is made just above the clavicle extending from the border of the trapezius to approximately one centimetre beyond the midline. (In the first attempt (Koch 1937) a vertical incision was made parallel to the sternocleidomastoid muscle; it proved to be somewhat unsatisfactory as it permitted but limited exposure of the caudal end of the sympathetic trunk.) The skin and adjoining platysma are separated from adjacent tissues and the cut edges are fastened with silk sutures so as to allow the maximum of gaping. The next step is a division of the clavicular portion of the sternocleidomastoid muscle. Its cranial portion is lifted and sutured to the already fastened upper edge of the skin. This procedure brings into view the

omohyoid muscle, the fascia colli media fat, and possibly some lymph nodes. The omohyoid muscle is transfixed by two sutures and divided, the sutures preventing either portion from getting lost. The removal or pushing away of the fascia colli media and adjoining fat and the division of the omohyoid muscle expose the scalenus anterior muscle with the phrenic nerve, the inferior thyroid artery, the ascending cervical artery, and the transverse cervical artery. After gentle blunt dissection the thyreo cervical trunk is brought into view. In some instances in order to get into the deeper structure it is not necessary to ligate the entire trunk; the ligation of the inferior thyroid artery suffices. The decision depends on the ease with which it is possible to retract caudally the subclavian artery. Without retracting the subclavian artery it is difficult to reach the vertebral artery with the accompanying sympathetic plexus.

Should it be necessary to ligate and cut the thyreo cervical trunk it is best accomplished by leaving a fairly large stump so as not to permit the slipping of the ligature. It is felt that it is always safer to put a second ligature just below the first.

The next step is to proceed with the division and ligation of the vertebral vein crossing obliquely from the medial aspect of the scalenus anterior into the pre-vertebral tissues. The ligation of the vertebral vein clearly brings into view the anterior aspect of the vertebral artery and medially to it the ganglion intermedium. This relation is not constant; occasionally the ganglion may be found laterally or anterior to the artery. A nerve twig from the sympathetic trunk to the stellate ganglion, the Ansa Vieussens, is seen going over the subclavian artery. It may be easily identified by applying traction which moves the subclavian artery. Using the Ansa Vieussens as the lead the sympathetic chain is reached. Once

the relationship is established the vertebral artery is stripped of its sympathetic plexus over an area of about one to two centimetres. The dissection is rendered fairly simple by use of a small sharp scalpel. When stripped the artery is pulled up and the underlying tissue examined. After lateral retraction of the scalenus anterior muscle the prevertebral fascia is divided. The stellate ganglion with its numerous branching fibres and occasional veins is then in plain sight. Careless cutting of a vessel in this region results in a brisk and obscuring bleeding. In carrying out the dissection the surgeon's action may be aided greatly by the introduction of the small spoon-like depressor A. The movement of the pleural dome on which is superimposed the costo cervical artery not only interferes with the visualization of the field but also may lead to an accidental perforation of the parietal pleura. It is self-evident that the dome must be detached from its costal and cervical attachments; this is best accomplished with the aid of a sharp thin scalpel. The costo cervical artery should always be divided and ligated. The extirpation of the stellate ganglion and of the vertebral nerve is accomplished in one step. The ganglion is grasped firmly by the Thiersch forceps and pulled inferiorly. The rim and the attachments are thus brought into light and may be cut from their upper end with sharp scissors. Once freed from the upper and posterior attach-

ments more forward traction is applied to the ganglion so as to permit the introduction of a finger between the sympathetic trunk and the posterior wall. With the finger as a guide the trunk is detached as far as possible and cut below the first costo vertebral junction, which is roughly midway between the stellate and second thoracic ganglia. If the operation is done with care, the field is dry and therefore closure may be accomplished without any drainage. If in doubt, a drain may be placed in the dependent portion of the wound. After the repair of the separated muscles the wound is closed in layers in the usual fashion. The patient is kept in bed for a period of about one week, and the other side may be operated on in approximately two weeks.

### Complications and Sequels

In the series of patients operated on by this method two fatalities have been observed. One was due to embolism, and the other patient died several hours after the operation of a brisk haemorrhage due to the slipping of the ligature from the thyreo-cervical trunk.

The anticipated Horner's syndrome was observed in every case, though enophthalmos had a tendency to regress,

becoming quite inconspicuous within a few months. The physiological complication to be expected is the inability of the heart to respond with acceleration to any muscular effort (the cardiac nerve is severed from its attachment when the stellate ganglion is removed). For about two months following the operation the patient must avoid any extreme exertion, as it may be accompanied by weakness and even collapse. Shortly after the operation some patients complain of pains in the shoulder and arm on

FIG. 3.—Cross section of the neck showing the interior approach to the stellate ganglion. 1 Sternocleidomastoid muscle (sutured end) 2 Sternocleidomastoid muscle (inferior portion) 3 Phrenic nerve 4 Omohyoid muscle 5 Clavicle 6 Scalenus anterior muscle 7 Subclavian artery 8 Lung 9 Vagus, carotid artery and internal jugular vein 10 Stellate ganglion

the side of the operation. The pain lasts but a few days, and usually requires no attention. In certain persistent cases it was found useful to inject a small amount of novocain into the brachial plexus right above the clavicle; this gave immediate and permanent relief. Another complication seen in about one-third of the cases is incontinence. Fortunately it is not lasting, and in our experience always disappeared after the first forty-eight hours. Occasionally there is a paresis of the upper extremity of the operated side lasting but a few days and leaving no residual effects. Two patients perspired copiously in the region of the abdomen, lower back, and lower extremities. So intense was the perspiration that it necessitated special nursing care. This lasted for a period of almost six weeks and responded but poorly to atropine.

### Results

The operation was performed on fifteen cases of disseminated sclerosis, of which ten may be considered for statistical study, six to fourteen months having elapsed

since the operation Eight of the ten patients are alive to-day

Practically every case including the four most recent ones responded favourably to this surgical procedure which is in agreement with the findings of Wetherell. At no time did we notice any immediate unfavourable effects in the development of symptoms. We attach considerable importance to this since trauma in cases of disseminated sclerosis is believed to cause aggravation of symptoms.

It would be premature to draw final conclusions regarding the ultimate possibilities of this treatment. Nonetheless we feel encouraged because in the majority of cases a remarkable degree of amelioration has taken place. It is not possible to attribute all the improvement to spontaneous changes in the course of the disease. All of the patients were in an advanced stage of the disease. We are attempting now to operate on patients in earlier stages when of course the evaluation of results will be considerably more difficult and not easily assessed.

This report attempts to deal primarily with the technique of the operation and so no detailed account will be given of every case. We feel that it is desirable to present the history of one of the patients in detail in order to give an idea of the type of case we have treated. Since the procedure is in the experimental stage we have so far applied it only to cases which respond to no other method of treatment. The case below is typical of this group.

### Case History

A man 39 years old presented himself for an operation at the Middleburg Hospital in June 1936 with the following story.

After an accident in 1926 when his right thigh was run over by a carriage he developed a paraesthesia of the injured side. The Wassermann and Kahn reactions were negative but there was a slightly positive Pandy test. Shortly after the first examination the patient developed some difficulty in walking. There was a slight tremor of the lower right extremity but there was neither nystagmus nor intention tremor. The speech was normal. The patient was given an arsenic and quinine preparation and asked to report for examination later.

An examination at the beginning of 1927 disclosed general aggravation of the symptoms. Paraesthesia became more pronounced and involved both of the lower extremities. Three years later in addition to the original complaints he developed pains in the right side and there was a marked decrease in

the muscular power of the right leg. The patient began to have difficulties with his vision and was frequently nauseated. Some six months later Romberg's sign became definitely positive rotary bilateral nystagmus was noted and there was a bilateral Babinski reflex. The patient was unable to move and most of his time had to be spent in bed. Examination in the middle of 1930 showed that the right Babinski reflex had disappeared but the nystagmus persisted. The patient developed spontaneous jerking of the lower extremities and there was pallor of both retinæ. The patient was no longer able to read. There was a marked stasis of the lower extremities and some retention of urine. In 1934 in addition to the aggravation of the symptoms present pains appeared in the lower limbs. The right leg could no longer support him.

In 1936 examination on the eve of operation revealed the following salient features: diplopia marked bilateral nystagmus temporal pallor of both optic disks inability to read scanning speech bilateral intention tremor of the upper extremities abolition of abdominal reflexes most of the time the patient had to depend on a catheter for the passage of urine both knee jerks were absent both plantar reflexes were extensor both lower extremities showed occasional pain.

Explanatory Note: Intensity of symptoms are recorded as follows:

taneous jerks, and there was a marked ankle clonus. The patient could not walk independently and was able to move about only with the support of two sticks, at best, the furthest he could progress by himself did not exceed ten metres, and even then he occasionally had to be supported. When moving the body was bent forward with the two arms stretched forward clutching the two walking sticks in front.

An operation was performed on the left side on June 25, 1936. On the first day after the operation he was unable to move his left leg, and incontinence was absolute. On the second day the spontaneous jerks in the left leg disappeared, though they were still present in the right leg. On the third day the patient was able to move his left leg. There was no change in the other symptoms.

The sympathectomy and ganglionectomy were performed on the right side eleven days after the first operation. On the following day the patient was no longer incontinent. The spontaneous jerks of the right leg were only slightly perceptible. Three days later they disappeared altogether. Paraesthesia of the extremities was no longer present. Two weeks later the patient tried to walk supported by a stick and a nurse. Twenty-four hours after the first attempt he was able to move about with a walking stick. For the first time in several months he was able to lift his legs independently. In about three weeks after the second operation the patient was able to walk without the help of the stick or nurse. The walking though fairly strenuous, was successful, although the gait was shuffling. Romberg's sign was negative. There was no ataxia. On the twenty-third day the patient was discharged from the hospital. He returned for examination a month later. He moved about independently with apparent ease, though he collapsed some six weeks after the operation following a walk of a few hundred metres. The examining physician stated that the pulse frequency was normal. The collapse necessitated a rest of a few hours, after which the patient felt normal. Three months later he was able to resume his former occupation as an assistant in a grocery shop. He was able to walk about, though he preferred to be supported by a walking stick.

Fourteen months later the patient is still able to walk with the aid of a stick. There is no diplopia. He is able to read. Romberg's sign is negative, and he has no pain.

### Conclusion

The case of multiple sclerosis just described was one with a definite downward course. The only transient improvement was in 1930, when the patient temporarily lost his right Babinski reflex. The operation has not only arrested the progress of the symptoms but has also re-established some of the functions.

We are presenting all our cases in tabulated form. Table A gives age of the patient, duration of the disease from the first observed symptom, number of remissions, duration of the final stage before operation. Table B gives the outline of principal symptoms and their changes. Space will not permit detailed consideration of each case. We have confined ourselves to the most distressing symptoms and to those common to most of the cases. Neither will the record of reflexes be given, since the surgical procedure only exceptionally modified the original findings.

The evaluation of the results in Cases 1, 2, 5, 10, and 12 is not included. No. 1 has already been discussed in detail. No. 2 because of a very unsatisfactory physical condition could be operated only on one side and died of uraemia eight months subsequently. Patients Nos. 5 and 12 died, one of pulmonary embolism and the other of a haemorrhage of the thyrero-cervical trunk. Patient No. 10, though showing progressive improvement in neurological symptoms died of intercurrent infection eight months later.

This paper deals primarily with the technique of ganglionectomy and sympathectomy by the anterior approach. Our experience with this treatment in advanced multiple sclerosis suggests the desirability of further trial of this therapeutic measure.

## THE TREATMENT OF PLACENTA PRAEVIA

### A REVIEW OF 286 CASES

BY

O. LLOYD, M.B., B.S.

AND

J. E. GIESEN, M.B., B.S.

*Late Resident Medical Officers, Queen Charlotte's Maternity Hospital, London*

During our respective terms of office at Queen Charlotte's Maternity Hospital we were much impressed by the results of a scheme in operation for the treatment of placenta praevia. The principle of this scheme was that all cases should be treated by a preconceived routine method. We found that its use greatly facilitated our work and, so far as we could judge, led to an improvement in the mortality rate of this grave condition.

### A Standardized Method

Standardization is obviously a desirable feature in dealing with certain emergencies, as it affords an opportunity of assessing the value of the treatment, and those who have to carry this out are "forearmed" with a knowledge of the immediate steps to be taken for the relief of the disaster. It would seem of value to publish the results of a standardized treatment of a condition for which such a variety of methods are advocated. Since this scheme was put into operation 143 cases of placenta praevia have been treated over a period of approximately five years. These cases we shall refer to as Group A. For purposes of comparison we have taken an equal number of cases immediately preceding the start of the scheme. This series of 143 cases will be referred to as Group B. The principles governing the treatment of cases in Group A were laid down by Mr. Leonard Phillips, who assumed responsibility for all cases of placenta praevia. He has kindly allowed us to publish an account of his routine treatment. In order to clarify this account the following definitions are given.

1. A central placenta praevia was considered to be present if the internal os was completely covered by placental tissue.

at the time of examination per vaginam the examination being made under anaesthesia and the finger passed round the whole internal os.

2. A marginal position of the placenta was held to exist if the edge of the placenta partly covered the internal os and the presenting part could be felt covered by membrane on the other side of the internal os.

3. A lateral position of the placenta was considered to be present if the edge of the placenta could only be felt with difficulty in the lower segment by the examining finger and the placenta did not encroach upon the internal os.

### Principles and Practical Aspects of the Treatment

The following account enumerates the principles and summarizes the practical aspects of the treatment.

1. In all cases of ante partum haemorrhage a routine clinical examination was made in order to exclude toxæmia. If this was negative the cases were then regarded as instances of low insertion of the placenta until vaginal examination had excluded this complication.

2. The blood group of all patients with a pulse rate of 100 per minute or over was determined prior to vaginal examination and preparations were made for transfusion.

3. Vaginal examination was performed under light general anaesthesia with the patient in the lithotomy position such examination being performed only after full preparations had been made for packing the vagina. The examination was made very carefully the state of the cervix being noted, and the lower uterine segments gently explored with the examining finger. Subsequent procedure varied according to the findings. If a central placenta praevia was diagnosed Caesarean section was the routine method of delivery and if bleeding occurred at the examination the vagina and cervical canal were packed with gauze until it was effectively controlled by direct pressure. Counter-pressure was effected by a tight abdominal binder and a T shaped perineo abdominal bandage. The condition of the patient was as a rule adversely affected by a combination of haemorrhage and shock resulting from the operation of plugging. The next step was to restore the general condition of the patient by morphine and blood transfusion. When this was considered satisfactory Caesarean section was performed irrespective of the state of the foetus. When either marginal or lateral placenta praevia was diagnosed the membranes were artificially ruptured whether the patient was in labour or not and as much liquor as possible was allowed to escape. This usually led to satisfactory descent of the presenting part and packing the vagina was employed only if bleeding was profuse or continuous.

4. In all cases replacement of blood loss by early and adequate transfusion was carried out.

5. The performance of external podalic version and pulling down a leg was regarded as unnecessary interference but where a complete breech presentation was encountered and the os was sufficiently dilated a leg was pulled down to effect pressure by means of the half-breech Willett's scalp forceps were employed in one or two isolated cases after the removal of the haemostatic plug.

6. Stress is laid on efficient packing of the vagina. The gauze employed was in the form of rolls 4 inches wide and 6 yards long. These were soaked in 5 per cent. dilute solution and were packed tightly into the fornices. Even additional roll used was tied to the end of the

preceding one. The average number of rolls was three for primigravidae and five for multigravidae. The packing was left *in situ* for twenty four hours or until it was expelled during labour by the presenting part. This latter desirable result was obtained in most cases. Catheterization of the bladder was usually necessary while packing was in position. The advantages claimed for efficient packing are (a) bleeding can be completely arrested and time is gained to restore the patient's general condition (b) the vascular sinuses exposed by placental separation are compressed and clotting can occur (c) while packing of the vagina in conjunction with artificial rupture of the membranes is a recognized stimulus to uterine contraction we have not found that unduly rapid delivery ensued. In a certain number of cases further bleeding occurred after removal of the packing but this was effectively controlled by repacking.

### The Case Results

We have arranged in tabular form the case results of Groups A and B. The stillbirth rate is included for the sake of completeness. Plugging the vagina is regarded by some authorities as a dangerous procedure owing to the increased incidence of sepsis. However since plugging has been an essential feature we feel that our account would be incomplete without a consideration of the degree and site of infection occurring after all forms of treatment.

## Consideration of Results

The 143 cases of Group A were treated according to the method outlined above, and from a study of the figures it is evident that

1 Many cases (38 per cent) required only artificial rupture of the membranes and the application of a tight binder. Such cases were lateral or marginal insertions occurring mostly in multiparae admitted in labour. Uniformly good results are to be expected in this type of case, and are obtained in this hospital and elsewhere.

2 Haemorrhage was profuse enough to require immediate steps to arrest it in about half the cases (47 per cent).

3 Plugging the vagina has proved an extremely successful method of achieving haemostasis.

We therefore venture to conclude that the striking decrease in the mortality rate in Group A is due to (a) the co-operation and team-work made possible by the standardization of treatment, (b) the prompt arrest of severe haemorrhage by plugging the vagina, (c) replacement of blood loss by transfusion, (d) treatment of shock before delivery of the patient. A comparison of the total morbidity rates for the two groups—Group A, 15.4 per cent, Group B, 14.7 per cent—reveals but little increase in the incidence of sepsis, and the difference in stillbirth rate is negligible.

Out of a total of 286 cases treated, 146 required active intervention per vaginam, excluding those treated by artificial rupture of the membranes only. Seventy-three of these cases were plugged and seventy-three were treated by either pulling down a leg with or without podalic version or the application of Willett's forceps. The plugged series showed two cases of severe and fourteen cases of mild genital infection and the other series two cases of severe and ten of mild genital infection. The increase in sepsis rate is therefore very small. It is interesting to note that Caesarean section was performed on six occasions from six to twenty-four hours after plugging, and that only one of these patients had a morbid tem-

perature, due to a femoral thrombosis occurring on the twelfth day. We feel that we are entitled to suggest that plugging the vagina for placenta praevia is not attended with an undue liability to sepsis when its morbidity rate is compared with that following other forms of treatment which involve intervention per vaginam.

## Summary

1 The results of treatment of 286 cases of placenta praevia are reviewed.

2 The standard method of treatment at Queen Charlotte's Hospital is described. Emphasis is laid upon the value of a preconceived routine, which included plugging and replacement of blood loss.

3 We believe that the improvement in the mortality rate is due to this method.

4 Evidence is offered in support of the contention that vaginal plugging in cases of placenta praevia is not associated with a high rate of sepsis when compared with that of other forms of treatment.

In conclusion we should like to thank the members of the honorary staff of Queen Charlotte's Hospital for the use of the case records, and in particular Mr. Leonard Phillips for permission to publish an account of his routine treatment. We also wish to express our appreciation of the work of the labour ward staff, to whose co-operation much of the improvement in results is due.

CONCERNING THE BOX MASK FOR  
OXYGEN ADMINISTRATION

BY

J. ARGYLL CAMPBELL, M.D., D.Sc.

(National Institute for Medical Research, Hampstead)

The main outline of this method of oxygen administration was originally described in the *Journal* about two years ago (Campbell, 1936). Since then some additional information (Barach, 1937, Campbell, 1937a, 1937b) has been published. A number of the masks have been used on patients and further data have been obtained, while various criticisms have arisen. These are dealt with below.

## Comfort of the Patient

With the earlier types of mask vision was rather restricted. In more recent types wider vision has been provided by removing the shoulders of the mask and shifting the inlet tube for oxygen from the front of the forehead to a horizontal position inside the mask as in some of the earlier experimental masks. Fig. 1 illustrates the transparent type made of celluloid acetate. This material is neat, but it is not durable and must be washed only in cold water, as warm water or exposure to the sun will warp it. This celluloid acetate is not very inflammable. More durable material is aluminium, which, although greater in cost, is perhaps more suitable for hospital patients. The oxygen enters the mask through perforations in the horizontal portion of tubing inside the mask. These perforations must be directed upwards so that the incoming oxygen strikes the middle of the top of the mask. A bobbin flow-meter records the rate of oxygen flow, and an automatic regulator is used for the cylinder.

Some patients have found the mask rather warm to the face. This was due in some cases to enclosing the chin within the mask. The opening at the back of the mask should be bent to include only the nose and mouth, and

the cheeks should be excluded. Thus only a small portion of the total area of the face is enclosed within the mask and on warm days more of the skin of the arms may be exposed to the external air to aid loss of body heat. The sensation of warmth is usually only temporary and is noticeable mainly during the early period of wearing the mask. In colder atmospheres some protection of the skin on the face, also the temperature of the skin of the enclosed portion of the face is not so high as that of the

FIG 1—Transparent (celluloid acetate) mask in position with bobbins flow meter and automatic regulator for gas cylinder (Photo by L. W. Collison)

clothed body. The opening at the back of the mask is lined with lint which is kept in position with adhesive plaster and may be easily renewed. Two or three folds of lint are used to keep the mask airtight against the nose and face.

Expectoration may take place through the lower open end of the mask if a wide mouthed vessel is used to collect the sputum. Food and medicine may be administered through a door on the front of the mask. An easier method during meals is to hold the mask in position by hand and remove it only at the brief periods when food is actually being placed in the mouth. In any case breathing usually ceases at this moment.

This type of mask has been used on some patients for prolonged periods up to six weeks without any greater discomfort than with other methods. Its advantages have been stated in the earlier papers. It has an advantage over nasal methods in that it may be used when the nasal passages are blocked. In emergency a box mask may be made from a cardboard box and a rubber tube in ten minutes (Campbell 1936).

### Oxygen Pressure Inside the Mask

Analysis of the gas inside the mask was carried out with Haldane's large apparatus using about 5 c.c. of the gas mixed with about 15 c.c. of nitrogen. Samples were taken either at the end of inspiration or of expiration by means of an evacuated sample tube to the upper end of which a fine bore glass tube filled with mercury was attached. The position in the mask from which the samples were withdrawn was important. It was 2 to 3 cm. to the right of the nose at a level of about 1 cm. above the opening in the right nostril. This point was regarded as being equally affected by the incoming oxygen at the top of the mask and the incoming air or expired air at the lower end of the mask. The gas obtained probably approximated in composition to that inspired by the subject under observation. The subject (C.P.) was 44 years of age, weighed 64.5 kg. and was 157.5 cm. in

height. His respiratory volume while sitting quietly under normal conditions was about 7.5 litres per minute. Two gases were used—pure oxygen and a mixture of 7 per cent carbon dioxide with 93 per cent oxygen. Fig. 2 records the results for oxygen pressure in percentages of an atmosphere with different rates of flow of the special gases. The oxygen percentages within the mask are slightly

FIG 2—Oxygen pressures at the end of inspiration and of expiration inside the mask just above level of right nostril with various rates of flow of gas

higher when pure oxygen is used than with the carbon dioxide mixture. Also as a rule the percentages at the end of inspiration are slightly higher than those at the end of expiration. With 6 litres of the special gases per minute the oxygen percentages in the mask are usually between 50 and 60 and with 1 litre per minute they are between 20 and 30.

### Oxygen Pressure in the Lung Alveoli

Using Haldane's technique samples of alveolar air were taken at the end of an ordinary inspiration immediately after removal of the mask from the face. Generally

FIG 3—Oxygen pressures in the lung alveoli with various rates of flow of gas

speaking the alveolar oxygen pressures (Fig. 3) are about 10 per cent lower than the oxygen pressures within the mask (Fig. 2). Thus at 6 litres of pure oxygen per minute the oxygen pressures in the alveoli of the lung are about 40 to 50 per cent. With the carbon dioxide mixture the alveolar oxygen pressures are slightly lower than with pure oxygen. The various masks tested give similar results.

Carbon Dioxide Pressure Inside the Mask

This was measured at the same point as the oxygen pressure inside the mask. The results (Fig 4) indicate that with 6 litres of pure oxygen per minute the carbon dioxide pressure averages about 1 per cent and does not rise

FIG 4—Carbon dioxide pressures at the end of inspiration and of expiration inside the mask, just above level of right nostril, with various rates of flow of gas

above 2 per cent. Most patients will not be affected by such concentrations of carbon dioxide. It is known from experience in submarines that discomfort is not noticeable until the carbon dioxide pressure reaches 3 per cent. Also, certain patients, according to the teaching of Yandell Henderson, are benefited by carbon dioxide as a respiratory stimulant, and he advocates from 5 to 10 per cent. To obtain about 5 per cent inside the mask it is necessary to use a mixture of 7 per cent carbon dioxide and 93 per cent oxygen at a flow of 6 litres per minute (Fig 4). Breathing about 5 per cent of carbon dioxide increased the volume breathed by the present subject from the normal figure of 7.5 litres to about 12 litres per minute, depth—not rate—of breathing was increased. With a more rapid flow and mixtures containing higher percentages of carbon dioxide, the carbon dioxide pressure in the mask may be further increased. In cases of carbon monoxide poisoning 10 per cent carbon dioxide with 90 per cent oxygen is advisable with this mask until respiration is well established, when pure oxygen should be used (Campbell, 1937a).

Carbon Dioxide Pressure in the Lung Alveoli

Fig 5 gives the results for carbon dioxide pressure in the alveoli of the lung under similar conditions. Normally the subject employed has an alveolar carbon dioxide pressure of about 5 per cent. The mask being worn and pure oxygen flowing from 1 to 6 litres per minute, the alveolar carbon dioxide pressure is usually somewhere between 5 and 6 per cent. The increase in alveolar carbon dioxide pressure above the normal is not necessarily due to the mask, because administration of oxygen at high percentage by any method tends to increase the carbon

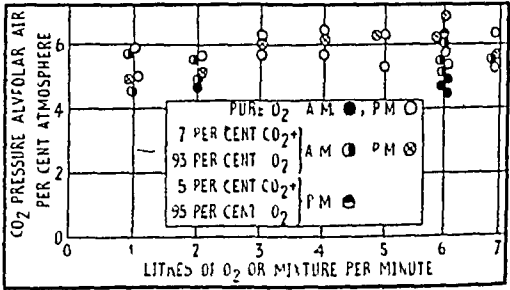

FIG 5—Carbon dioxide pressures in the alveoli of the lung, with various rates of flow of gas

dioxide pressure in the tissues, and similar alveolar carbon dioxide pressures are obtained with other methods. With 6 litres of pure oxygen the alveolar figures are usually lower one to three hours after lunch compared with samples taken four hours after breakfast. Such variations are connected with the acid base changes concerned with digestion or other factors. At 6 litres per minute, and with the mixture of 7 per cent carbon dioxide and 93 per cent oxygen, there is a slight further increase in alveolar carbon dioxide pressure.

All the observations recorded in the charts in Figs 2 to 5 were made in a room with the temperature purposely on the warm side—that is, at about 20° C and with thermometer cooling power 5 to 6, with air velocity usually between 20 and 40 feet per minute. These are fairly comfortable indoor conditions for a patient in summer weather.

Position of the Mask and Effects of Draught

In draughty wards the mask should be adjusted so that its lower front edge is about 3 cm. above the chest, or the head of the bed should be screened. As pointed out before

Table showing Effects of Draughts and Their Correction. O<sub>2</sub> Flow 6 Litres per Minute

Expt No	Date	Temp °C	Cooling Power	Air Velocity (ft per min)	Alveolar Pressures per cent atm		Conditions of Mask		
					CO <sub>2</sub>	O <sub>2</sub>	Mask	Curtain Used	Position (cm above chest)

7b					5.9	35.8		Cardboard and	
7c					5.7	35.0			
7d					5.8	28.8		Nil	

(Campbell 1937a) if the head is raised so that this edge is 10 cm above the chest the efficiency of the mask is affected somewhat by draughts so that with 6 litres of pure oxygen per minute the alveolar oxygen pressure is about 30 to 40 per cent in place of 40 to 50. The chest acts as a damper to draughts so that with the mask near the chest less oxygen is lost from the mask and fewer draughts of air enter the mask. In patients with a long neck the mask may be made longer and narrower without change in volume of inside space but a simpler correction is to partially close the bottom of the ordinary mask (see Table Experiment 5).

Dr R. V. Christie also kindly pointed out that draughts affect the efficiency to some extent. My results for the effects of draughts are given in the table using oxygen flow of 6 litres per minute in all cases.

With an air velocity of 40 feet per minute and the front edge of the mask 3 cm from the chest the alveolar oxygen pressure is about 40 per cent (Experiment 2) with an air velocity of 160 to 200 feet per minute the oxygen pressure is lowered to about 30 per cent (Experiments 1 and 3). The effect of such a draught is easily countered by fixing with adhesive tape a curtain of lint about 5 cm in length all round the bottom of the mask as in Experiment 4 in the table: the alveolar oxygen pressure is 45 per cent in spite of an air velocity of 210 feet per minute.

In Experiment 5 with the head held up and the mask 10 cm from the chest the alveolar oxygen pressure is kept at a high level 53 per cent by closing the lower end of the mask with a cardboard grid containing air spaces 1 cm square alternating with portions of solid cardboard of the same dimensions. In Experiment 6 with lower air velocity it is shown that no closure of the bottom of the mask is required. In Experiment 7d in the table with an air velocity of 215 feet per minute and the lower edge of the mask 10 cm from the chest and the bottom of the mask freely open the alveolar oxygen pressure is lowered to about 29 per cent but by means of the perforated cardboard grid or by closing two thirds of the lower end of the mask with a piece of entire cardboard the alveolar oxygen pressure is raised to about 35 per cent (Experiments 7a, 7b and 7c). The curtain of lint is the most efficient means of protecting against draughts but under ordinary circumstances the head of the bed may be provided with screens so that no special closing of the lower end is required. If the patient is restless and moves the head about much then the bottom of the mask may be closed by one of the above methods to gain greater efficiency. Even at the worst with the bottom of the mask open and in a draught the patient is still getting oxygen in the lungs at a pressure of about 30 per cent—that is more than double the normal—with a flow of 6 litres of oxygen per minute.

For sedentary individuals Sir Leonard Hill and others have recommended air velocities of 3, 7 and 17 metres per minute with air temperatures 15, 18 and 21°C respectively. Under these conditions the mask gives about 40 to 50 per cent of oxygen in the alveoli of the lungs with a flow of 6 litres of oxygen per minute.

Dr A. L. Barach (personal communication) uses a small injector on the oxygen inlet tube so that some air is drawn in: this increases the flow through the mask which is reduced in size. This draught helps to remove carbon dioxide and cools the face but may be too rapid and so disturb certain types of patients. He uses also a whistle arrangement which gives warning when the

oxygen tube is kinked. He recommends the apparatus for patients and for passengers in aeroplanes (Barach 1937).

### Summary

1. The recent type of mask made of aluminium or transparent celluloid acetate for oxygen administration is described. Vision is now much wider. The comfort of the patient is considered.

2. With 6 litres of pure oxygen per minute the oxygen pressure in the alveoli of the lung is kept at about 40 to 50 per cent under ordinary comfortable conditions of ventilation.

3. With 5 litres per minute of a mixture of 7 per cent carbon dioxide and 93 per cent oxygen the patient breathes about 5 per cent of carbon dioxide and the alveolar oxygen pressure is about 40 to 45 per cent. This or a similar mixture may be used when a respiratory stimulant is required.

4. The effects of draughts and of the position of the mask on its efficiency are considered. Simple means of countering effects of excessive draughts or excessive movement of the head are given.

I am indebted to Mr C. Perarde who acted as subject in the observations. The mask may be obtained from Messrs Siebe Gorman and Co. 147 Westminster Bridge Road SE 1.

## INTRANASAL APPLICATION OF POLLEN SOLUTION IN HAY FEVER

By

CLEMENT FRANCIS, M.A., M.B., B.Ch.

Surgeon Metropolitan Ear, Nose and Throat Hospital

The object of this short article is to describe a method of treatment which I have found useful during recent years in relieving hay fever. I have employed it in numerous cases either alone or in conjunction with other means and I find it invaluable both as a preventive of attacks and for use in relieving an already existing attack.

### Technique

The method is extremely simple and consists in spraying the nasal cavities with a few drops of a sterile solution of grass pollen. The solution should be applied to the septum, the middle and inferior turbinates and in particular to any hypersensitive areas. It is this done during the season in the case of a hay fever patient the immediate effect will be to produce a short bout of sneezing followed by the usual symptoms of hay fever. The effects of this artificially produced attack quickly subside and the patient then becomes more resistant to the pollen in the air with the result that for several days to a week or more many patients remain free from all symptoms of hay fever. The procedure may be repeated if necessary then be repeated.

The method above described may with advantage be used in conjunction with other means of treatment and if there are any abnormally sensitive areas in the nose I make it a practice to treat these (Francis 1934) before applying the pollen solution. It carefully carried out both

methods may be employed on the same occasion, with the result that not infrequently no further symptoms of hay fever will occur during the remainder of the season. The strength of the different pollen solutions employed depends on the severity of the symptoms in any particular case, as well as the weather conditions. In severe cases, in hot weather, small doses should be used.

### Seasonal Treatment

In an average case seen during the hay fever season, with mild symptoms, an initial dose of 10 units of pollen solution may be given intranasally, and if this does not produce mild sneezing within five minutes the dose may be repeated. Subsequent doses may be increased by 25 per cent at intervals depending on the length of time during which the patient remains symptom-free. In some cases no subsequent dose is necessary. It is convenient to arrange that the desired dose is contained in 0.25 ccm to 0.5 ccm of fluid, as this is a suitable amount to apply at one time. Necessary dilutions of concentrated pollen solutions may be made with carbolic saline (0.5 per cent phenol in normal saline), and the dose measured in a graduated medium sprayer.

If on any occasion there is pronounced local reaction, the dose should not be increased at the next application, but the same dose again given, when the local reaction will be decidedly less than on the previous occasion. After this the next dose can again be increased by 25 per cent, as a rule without resulting in any great reaction. It is difficult to lay down any hard-and-fast scale of doses, as patients vary considerably in their response to different pollens, and also in their response to the same pollen under varying conditions of weather. In hot dry weather the local reaction produced by a given dose of pollen solution will be greater than that from the same dose received by the same patient in cold wet weather. All the above factors must be taken into account when considering the best dose for any particular occasion.

It is important, so far as is possible, to include in the pollen solutions employed all the grass pollens to which the patient chiefly reacts, for a patient may, after several applications, be made quite immune to a concentrated solution of one kind of grass pollen, although a different type of grass pollen of a lesser concentration sprayed into the nose may still produce sneezing and other hay fever symptoms.

It has constantly been observed that if the same dose of the same pollen solution has been sprayed into the nose of any patient on two or more occasions at intervals of a few days or a week, or even longer, the hay fever symptoms produced have become progressively less on each occasion.

### Pre seasonal Treatment

Before the hay fever season begins larger doses may be given, and in an average case doses of 100 to 200 units of pollen solution may be sprayed into the nose to commence with, followed by a 30 per cent increase at intervals of two days or more. These doses do not as a rule cause more than slight transient symptoms of hay fever, and there is no doubt that the pre seasonal intranasal application of pollen solution increases the patient's resistance to pollen. Mackenzie (1922) has reported favourably on this method, and Caulfield (1922) has published good results from pre seasonal intranasal inoculation with pollen ointment although neither author claimed that the method by itself produced complete immuniza-

tion. I have never seen any untoward symptoms develop as a result of applying pollen solution in the way described, either before or during the hay fever season.

It is better to allow the artificially produced attack to subside naturally than to attempt to clear the nose immediately by the application of powerful vasoconstrictors, for in the latter case, although the nose may become temporarily clear, congestion usually returns after one or two hours, and it then remains obstructed for a longer period than if it had been allowed to clear naturally. As a rule, if left alone, all symptoms of the artificially produced attack completely cease in from ten minutes to one hour.

### Conclusions

The advantages of intranasal inoculation in hay fever are that it can conveniently be used in conjunction with other methods, that it provides a means of giving relief to patients during an attack, and that it increases the resistance to pollen of patients who are intolerant of injection methods.

While it is not asserted to be a method which by itself results in complete cure, it can often be advantageously employed in cases where other means have failed or have only been partly successful.

## Clinical Memoranda

### Treatment of Diphtheria

During the period 1935-6 I gradually came to think that the early deaths in cases of diphtheria could not be due to a toxæmic condition, but more probably to some underlying infection which was earlier in operation than the toxin of diphtheria. This view was taken by reason of the early cardiac involvement, such as the quick pulse, the onset of pericarditis, the haemorrhagic rashes, the early nephritis, and also the haemorrhagic edge of the diphtheritic membrane, to name but a few of the earlier symptoms noted in severe cases.

In support of this view were the more definite effects of the toxæmia of diphtheria, as instanced rather in the later stages (when it is admitted as a definite toxic condition), such as the slowing of the heart and the other paralytic symptoms. I thought that the more likely infection to produce these earlier symptoms would be caused by an organism common to the throat and associated with early cardiac and renal involvement. It appeared that the most likely organism—a common cause of faucial, cardiac, and renal disease—would be a streptococcus, probably one of the hemolytic type. In view of this, on January 22, 1936, I decided to try the effect of treating both a diphtheritic and a streptococcal condition.

The first case this was tried on was a girl aged 15 who was admitted to hospital on the second day of infection. She was cyanosed with a rapid running pulse with petechiae all over the chest and neck and with extensive membrane surrounded by a haemorrhagic areola. She was given on admission, 100,000 units of anti diphtheritic serum and also 20 ccm of

and puerperal serum. The following day she was given 50 ccm of anti-diphtheritic serum and a further 20 ccm of anti-typhoid serum. She made an uninterrupted recovery.

It is interesting to note that this girl's two brothers died within seventy-two hours of being taken ill with diphtheria. Following this ill severe cases were given varying amounts of either anti-typhoid serum or anti-scarlet fever serum. Towards the end of 1936 there were several cases of cross infection with scarlet fever and it was decided with the full approval and consent of the medical officer of health (Dr Parry Pritchard) that 5 ccm of anti-scarlet fever serum should be given to all cases of diphtheria on admission.

This procedure has been carried out during the whole of the year 1937 (except for three cases where the medical officer in charge of the cases did not wish the anti-scarlet fever serum given). Severe cases however were all given increasing doses—10 ccm or more—of anti-scarlet fever serum where it was considered necessary. During this period 209 cases of diphtheria were admitted to the hospital. Of these only one died. This patient however was admitted on the fifth or sixth day of illness and prior to admission was more or less of an invalid with cardiac trouble following rheumatic fever when very young. She was ten years of age and died within twenty-four hours of admission. Of these 209 cases eleven were cases of laryngeal diphtheria.

I feel that this low death rate should be brought to the notice of those concerned in the treatment of diphtheria. Research might possibly identify streptococci in the blood in early cases of severe and/or haemorrhagic diphtheritic cases.

## A Severe Case of Chicken-pox with Some Unusual Features

A small outbreak of chicken-pox recently occurred in the scarlet fever ward of the Blackburn Corporation Hospital due to the admission of a case incubating the disease. All the secondary cases were of a mild type except the one to be described which was of an unusually severe nature and showed many interesting features.

### CASE RECORD

A boy aged 34 became ill on November 29 1937 and the following day was removed to hospital suffering from a mild attack of scarlet fever. There was no history of any previous illness. The disease ran an uneventful course there being no complications other than slight excoriation of the nostrils. The patient who was unvaccinated was a chicken-pox convalescent and on December 28 1937 (the thirtieth day of the scarlet fever) the first vesicles were noticed. These continued to come out steadily in crops and by January 1 1938 the eruption was extensive and in character and distribution very typical of chicken-pox. There was no inflammatory condition of the throat and no vesicles were present upon the buccal mucous membrane.

By January 3 his condition was worse and gave cause for anxiety. Towards evening a group of petechial haemorrhages could be seen covering an area of approximately two square inches on the front of each wrist. For the following two days his condition was grave. Petechial haemorrhages were now noticed on the trunk and limbs but were most profuse around the wrists and forearms. Fresh chicken-pox vesicles were still appearing and in fact continued to do so until January 13. Two areas one on the scalp and one on the face showed fairly extensive ulceration. The heart and lungs were normal and the urine at this time scanty but clear.

The latter was tested daily and on January 6 showed a faint trace of albumin (this was ten days after the onset of the chicken-pox and thirty-nine days after the onset of the scarlet fever). During the next few days the albuminuria increased and there was now a considerable degree of oliguria. The patient was drowsy and remained gravely ill until January 16 when some improvement in his condition was noticed although there was still profuse discharge from the ulcerative areas. From this date he made slow but steady progress towards recovery. The albuminuria persisted but by February 12 the urine was clear and the ulcers had practically healed.

### COMMENTARY

The interesting points in this case are (1) the severe nature of the disease as shown by the general toxæmia, petechial haemorrhages and ulceration; (2) the fact that fresh crops of vesicles occurred for no less than seventeen days; (3) the occurrence of nephritis. Haemorrhages in chicken-pox vesicles have been described by Healy (1936), Wanklyn (1922) and Whitaker (1915) and the term haemorrhagic chicken-pox applied to these cases. According to Goodall (1923) however cases showing petechial haemorrhage into the skin as in the case described also fall within this category.

The case certainly comes under the definition of ulcerative chicken-pox and it is interesting to note that Ker (1929) found this condition exclusively in convalescent scarlet fever cases.

Nephritis is described as a rare complication of chicken-pox and we regard the severe attack of the latter as a more likely cause of the nephritis in this case than the initial attack of scarlet fever although the possibility of a post-scarlatinal complication cannot be entirely ruled out.

### Summary

A convalescent scarlet fever case while in hospital contracted a severe attack of chicken-pox showing the unusual features of petechial haemorrhages and ulceration. Nephritis occurred as a complication. Fresh crops of vesicles continued to appear for the abnormally long period of seventeen days.

We are much indebted to Dr V. T. Thierens (medical officer of health) for his permission to publish this case.

The eighteenth report of the Joint Council of the Order of St. John and the British Red Cross Society covers the year 1937. In his foreword the chairman Sir Arthur Stanley pays tribute to the late Dame Sarah Swift whose death has deprived the Joint Council of one of its most active and efficient members who was loved and respected by all who knew her. Among many other matters an account is given of the work of the Central Bureau of Hospital Information established in 1920 with the co-operation of the British Hospitals Association. The expansion of its activity proves that it meets a definite need. One very useful service is publication of the *Hospitals Year Book*. Copies of the report may be had from Joint Council House 12 Grosvenor Crescent S.W. 1.

## Reviews

### NEW WORK ON IMMUNITY TO TRANSPLANTED TUMOURS

*The Influence of X-Radiation on the Development of Immunity to Heterologous Transplantation of Tumours*  
By Johannes Clemmesen Translated into English by Robert Fraser (Pp 160, 13 photographs, 8 tables, 12 charts 10s) Copenhagen Levin and Munksgaard, London Humphrey Milford, Oxford University Press 1938

This monograph describes important research work bearing on immunity to transplanted tumours. As is well known, attempts to make successful grafts of a tumour growing in one species of mammal into an animal of a different species have hitherto been almost always unsuccessful. It is now shown that rats can be made temporarily susceptible to implants of certain mouse tumours by previous exposure *in toto* to strong x-radiation. The effect is not permanent, and after two to four weeks the engrafted tumours disappear. That actual growth has nevertheless occurred is proved both by the size attained by the implants and by the muscular invasion by neoplastic cells. When regression has taken place the rat is immune to further inoculations, and this immunity cannot be destroyed by subsequent exposures to x rays. If the rats are irradiated four to five days *after* implantation, the effect is less marked than when they are irradiated beforehand, this is probably because the cells of the implant have already been affected by the normal defence mechanism against foreign tissue elements. It does not seem to matter if the irradiation is carried out immediately or several days before the implantation is made. By varying the x-ray dose it is found that with bigger doses the implants attain a larger size and persist longer than when the dose is smaller. The general conclusion drawn from these experiments is that irradiation delays the mobilization of the normal defensive forces until the graft has produced enough reaction against itself to inhibit further growth and to cause regression. The author concludes that at least two factors are concerned in the production of this immunity to foreign cells, of which one is affected by the x rays, while the other is not. Special care has been taken throughout these experiments to ensure uniformity of experimental conditions and accurate standardization of dosage.

### THE PHILOSOPHY OF SCIENCE

*What Science Really Means. An Explanation of the History and Empirical Method of General Science* By Julius W. Friend and James Feibleman (Pp 222 7s 6d net) London George Allen and Unwin Ltd

If men of science and general readers do not know what science is about it is certainly not for want of books on the subject. In the book before us Messrs J. W. Friend and J. Feibleman set out to tell us *What Science Really Means*, and the wrapper of their volume advertises two other volumes, to which six Fellows of the Royal Society have contributed, apparently having much the same laudable object. Messrs Friend and Feibleman, even if by summarily dismissing many writers of ability as logically confused or incompetent they sometimes irritate the reader, have produced an interesting volume.

They hold strongly that we ought to have a sound philosophy of science, but candidly face the common sense objection that scientists who adhere to different philo-

sophical interpretations do not disagree about their scientific work. "Does this mean, then," they ask, "that the question of the reality of the scientific subject matter is meaningless?" Perhaps this *ad captandum* question suggests a certain defect of philosophical method. Because sincere Protestants and sincere Catholics are often patterns of Christian virtue, sensible people do not ask rhetorically whether there is any meaning in the difference between the two religious systems. The analogy is indeed relevant to our authors' undertaking, they argue, we think correctly, that a difference of philosophical standpoint may affect the growth of science and must affect the attitude towards science of the outsider. They point particularly to the so-called social sciences as the victims of a false philosophy. Their general argument that scientific method is uniform, that there is no antinomy between empiricism and rationalism, no warrant for holding that induction is *the* method or deduction *the* method of progress, we take to have been proved by the practice of all investigators. We doubt whether, *in practice* there has ever been any disagreement on the point. It is not probable that the Empiricists whom Galen abused really did medical "experiments" at random, really tried everything impartially. It is quite certain that Galen, with all his love for philosophical general principles, did many odd experiments, with no other reason than to gratify his curiosity—which, as Karl Pearson once said, is the dominant motive of any real researcher.

When the reader comes to the end of the book, to the future, he may have legitimate doubts whether any philosophy, whether the most eloquent exposition of what science means, will be comforting. "There is a deadly logic involved between the given stage of a social order and the given stage of science. Though some small leeway may be allowed, their ability to separate is definitely confined within certain limits. Therefore the understanding of science on the part of a society is requisite for both science and society." That any large part of society will "understand" science any better than the mother of Zebedee's children "understood" the Master's doctrine, or will ever think of science as anything but a means of increasing the *commoda vitae* is improbable. Tolerance, not understanding, is the best we can expect in any society which, like most existing societies, is ruled not by reason but by emotion. The danger is that toleration, as a practice, is by no means secure even in the countries where it is most praised, and is extinct elsewhere. Even our authors implicitly (on p. 199) commend pure science to the public on the ground that in the long run the purer science is the more likely is it that practical results will be obtained. Few can now be found to defend scientific pursuits explicitly on the ground that it is interesting to "find things out," whether the "things" are of any practical importance or not. Such an argument can only secure a hearing in a tolerant society.

### HEALTH ADVICE FOR THE LAITY

*Brush Up Your Health* By Hugh Clegg M.A., M.B. MRCP (Pp 119, with 20 drawings by Ward, and diagrams 2s 6d net) With a foreword by Lord Horder London J. M. Dent and Sons Ltd 1938

One of the major problems of public health to-day is that of making medical knowledge available in useful form to the general public. Medical science is very rich, but its only really profitable employment is in prevention. Most ill-health is caused by human ignorance and folly. The need for sound and attractive books on the everyday realities of health and illness is not nearly met. There

is a great deal of rubbish written by persons who are not medically qualified and have besides this negative handicap the positive one of being obsessed with some unbalanced prejudice in favour of a particular regime. Dr Clegg's little book is a breath of fresh air. It has the great advantage that it is written by a doctor with wide knowledge of recent discovery and current knowledge and with a grasp of the application of this vast mass of learning to the simple facts of bodily health. Moreover the author's experience in presenting information saves him from the error of being schoolmasterish. He says what he has to say in a conversational manner that makes the easiest reading and he enlivens his discourse with quiet humour. The incongruous little illustrations also add much to the book as a good sauce improves food. In the first chapter he tells the reader how to take stock—how to find out how much health he already has by means of a searching little questionnaire. The reader apporions marks as he thinks fit and then adds up the score. After that Dr Clegg deals in detail with the principal constituents of diet with alcohol and tobacco obesity, sight, constipation and teeth. A sudden page of laxative advertisements is typical of his happy employment of humorous surprise to hold the attention. The chapter on "Bringing up your Children" is full of condensed wisdom and that on "Bringing up Yourself" of applied psychology. Exercise, the skin, milk, preventive inoculation and the fear of disease are only a few of the other subjects treated by a rapid fire of fact, sound inference and helpful suggestion. This little work contains an incredible amount of meat and a few tough bits which those who take a different view will reject. Moreover some of his advice would seem to postulate an independence and a prosperity which only a smallish percentage of the populace possess and in fact he goes so far as to counsel. To diminish the risk of getting cancer of certain exposed sites take care to get into or remain in the upper and middle class (that in which the incidence of such cancer is least) and not to fall into the class of unskilled workers. But on the whole the book is a valuable contribution to the task of securing that intelligent co-operation of the lay public without which the doctor can do little good.

### A HISTORY OF NURSING

*The Story of the Growth of Nursing—as an Art, a Vocation and a Profession*. By Agnes E. Pavey, SRN. With a Foreword by Sir John Weir, K.C.V.O. (Pp. 426, 15s net). London: Faber and Faber, 1938.

The how and why of any sphere of human activity are always of interest. The origins and growth of medicine, the early attempts at the care of the human body, whether of helpless infants or of the feeble and aged or of the injured and sick, are subjects of interest to all who ponder the development of the social side of human life. Indissolubly linked with this is the growth of nursing as a necessary part of the provision for human care. Miss Agnes Pavey's book gives as inclusive and informative an account of the birth and development of each phase of nursing from the earliest to the present time as we have read. She shows what widely diverse external factors have influenced or determined the lines upon which nursing grew and how greatly social factors and historical events have directed that growth.

After an introduction showing the influence upon pathology and medicine of primitive religion of superstition and folk lore of early ideas and of wars and of religious prohibitions, the author proceeds to the gradual discovery of the right causes for phenomena in the human

body and in the world around. Then follows a rapid but very effective and interesting review of the records of the conditions of the ancient world—in Crete, Chaldaea, India, China, Greece—and so to the strong humanitarian influence of the early Christian Church through the Middle Ages until the resurgence of nursing in the nineteenth century. The author shows that although the seeds of modern nursing were sown in the remote past its full growth did not occur until recent times. Now there is no part of the world where good nursing is not valued and desired. She adds that nursing offers a wide sphere of useful and interesting activity to the women of our land. It is no longer the expression of a mystic art possessed only by the favoured or the gods or demons. Nor is it a work of self-abnegation or religious fervour undertaken as a penance or for spiritual solace and uplift nor even is it entirely a selfless answer to the call of human suffering. Much less is it a shunned and rather repulsive activity of the ignorant woman to whom no other calling is open. It has been all of these. But Florence Nightingale made it a dignified secular profession for which a thorough and arduous training is necessary.

The book is well written, it is most entertaining to read. We can conceive few more suitable gift books likely to captivate the mind of young women who are wavering in their choice of professional work.

### NEURO-OPHTHALMOLOGY

*Neuro Ophthalmology*. By R. Lindsay Rea, B.Sc., M.D., M.Ch., FRCS. (Pp. 568, 141 figures, 19 coloured plates. A coloured frontispiece, 42s net). London: W. Heinemann (Medical Books) Ltd., 1958.

To the sprawling and unsystematized literature dealing with the borderland of neurology and ophthalmology Mr Lindsay Rea has added a comprehensive volume which makes a brave attempt to bring together a diffuse mass of information. As such his book is to be welcomed and his industry can only command respect. There is much in this volume that will be new to expert ophthalmologists and neurologists and not a little that should be known more widely than it is. There is so much in the book that is helpful that the reviewer is loath to draw attention to its serious defects. The material collected covers such a wide range that analysis, assessment and critical systematization are essential. The collection of facts is a starting point of a comprehensive treatise but not by any means its end. The facts are here but the critical survey is almost completely lacking, making the book essentially a collection of raw material. Innumerable and lengthy extracts from different authors, very often saving the same thing in different words, a loose style in introducing these extracts and but little attempt to reduce the mass of opinions into a coherent statement of fact are features to be found with distressing frequency. It is creditable to give acknowledgment to writers on the subject but when this is carried to the length of almost religious veneration for every passing statement not always original or illuminating the reader has a burden which he should not be asked to shoulder. The consciousness of unity and balance that are the essential feature of a book as opposed to a systematic collection of printed abstracts are sadly lacking. Yet as already pointed out *Neuro Ophthalmology* contains a vast amount of useful information not readily available. As a starting point for anyone who wishes to follow up the literature on some clearly defined aspects of neuro-ophthalmology it can be recommended without reserve.

As a critical survey clarifying issues and hammering out broad principles in an important and ill-defined subject it leaves much to be desired

### COAL GAS, BENZPYRENE, AND CANCER

*The Cause of Cancer* By David Brownlie BSc (Pp 208 7s 6d net) London Chapman and Hall 1938

The author of this book is a chemist with special knowledge of low-temperature carbonization. His thesis is very simple. Benzpyrene has been proved to possess carcinogenic properties, it is formed during destructive distillation of coal in the manufacture of coal gas, it is known to be present in coal tar and *may* be present in coal gas, if it is present in coal gas it *may* escape combustion and contaminate food cooked in gas-stoves and give rise to cancer among the urban population who live largely on food cooked in gas stoves. After chapters devoted to inaccurate generalities and fallacious statistics the author proceeds on the assumption that benzpyrene is in fact, present in coal gas and does escape combustion when gas is burnt, and that consequently benzpyrene causes cancer. Arguments as plausible and as silly could be brought forward to show that electric stoves cause cancer. Thus ultra-violet radiations cause cancer, the electric stove may give off ultra-violet radiations, the use of electric stoves has increased during the last twenty years and cancer has also increased during the last twenty years, therefore electric stoves cause cancer.

It is surprising that a scientific man did not first of all determine definitely whether or not coal gas does contain benzpyrene and if it does, whether or not the benzpyrene is destroyed when coal gas is burnt. The reviewer has had this point determined for him by chemists, and the answer is that coal gas does not contain benzpyrene and that when benzpyrene is added artificially and the gas is burnt the benzpyrene is destroyed. The author of the book ought to have acquainted himself with the facts concerning benzpyrene as a carcinogenic agent, it is established beyond all doubt that application of benzpyrene to the skin causes skin cancer in some species of animals and injection subcutaneously causes sarcoma, but that ingestion of benzpyrene has no effect.

This book is likely to cause unnecessary fear and even alarm among the general population, already sufficiently oppressed by the dread of cancer.

### Notes on Books

In his pamphlet *The Evolution of Chronic Rheumatism with Impairment to Correspond* (H K Lewis and Co, 2s 6d) Dr R FORBES FOWLER makes a plea for a more rational treatment of this important condition. No one treatment is likely to be suitable at all stages of the disease for the patient changes not only his manifestations but also his reactions to remedies in the course of years. Obviously prevention is better than cure, and for this purpose the author pleads for the establishment of clinics at which frigid-sensitive people can be trained to react against changes of temperature by means of contrast baths.

Dr E PILLET's book *Analyse Physique des Calculs Urinaires et Biliaires* (Paris, Masson, 25 fr) presents the results of an entirely new form of study in relation to pathological material. The methods of the science of crystallography have been applied to the elucidation of the structure of crystals and calculi. The outcome is an enrichment of our knowledge in regard to intimate detail, though the basic conclusions which have already been formulated using the cruder methods of proximate

chemical analysis are not found to be in need of fundamental alteration. The volume is illustrated by a number of very striking photographs showing in minute detail the crystalline structure of various forms of calculi, both urinary and biliary.

*Studien über die Prognose der Okkulten Kindertuberkulose*, by Dr GILLIS HERLITZ is a reprint from *Acta Paediatrica* Volume XIX, Supplementum II, and is published at Uppsala by Almqvist and Wiksell. The author of these studies on the prognosis of occult tuberculosis in children re-examined 1,457 children under 15 years of age, of whom about half had been Pirquet-positive and the other half negative, after a lapse of some ten to fifteen years. He concludes, as the result of his investigation, that a child who is tuberculin-positive but free from tuberculous disease beyond a primary complex—that is, a child suffering from occult, not manifest, tuberculosis—under normal conditions is more likely than a tuberculin-negative child of the same age to acquire a manifest tuberculous disease within the following ten to fifteen years, and to die from it. This increased danger continues for the child suffering from occult tuberculosis after it has reached adolescence. And so it is a greater disadvantage, at least for the first two to three decades of life, to have been infected with the tubercle bacillus in childhood than if the infection occurs later on.

Reprints of papers on research work from the wards and laboratories of the London Hospital during 1937 have been bound together in paper covers and the volume is obtainable from Messrs H K Lewis and Co at 7s 6d.

### Preparations and Appliances

#### MATTRESS AND BLANKETS FOR FOWLER'S POSITION

Dr CHARLES C BREWIS (Mippowder, Dorset) writes: The accompanying rough sketch illustrates my idea of an easy, quick, and efficient way of obtaining and maintaining Fowler's position, so frequently required for the nursing of acute cases of many kinds. I can hardly hope that the idea is original, but I have not seen it used during my twenty-five years' experience, nor have the several doctors to whom I have explained it.

The mattress is arranged as illustrated and two blankets are used to keep it in position, one is laid the full length

of the bed and the second is partly draped over the head of the bed and partly laid over the first blanket. The second blanket is then drawn over the fold in the mattress at the head of the bed and the first blanket is turned back over the head of the bed. The second fold in the mattress is thus helped to keep it in position. The first blanket is indicated in the sketch by a lined area and the second one by the stippled or dotted area. The cavities are filled with pillows or sandbags and the free end of the mattress can be prevented from slipping by the addition of a biscuit or, in fact anything to make up the bed. Pillows can be arranged on either side as arm rests. The arrangement is a great improvement on the 'donkey', it is simple and it works.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 11 1938

## RECREATION FOR THE WORKERS

The span from primitive magic to modern medicine covers not only a qualitative but a quantitative change. If it be true that environment exercises a profound effect on health through an almost bewildering range of physical and mental influences then it becomes a problem to define the limits of medicine in a highly complex world. As each new development takes place we find convincing evidence that health is affected for better or for worse. If health is affected medicine is involved. Where does it end? Are we deploying our forces over too wide a field? There is a limit to the interests that each of us can embrace without loss of efficiency in regard to the hard core of medical practice—namely alleviation of distress and assistance to the healing powers of Nature. But the limit is widely set and it must be admitted that few reach out fully to explore it. Those who do so find that the greater the mastery they acquire over fields of interest outside medicine the greater is their power to understand the forces that operate on their patients the greater becomes their power to advise and the more fully do they exercise the preventive and constructive sides of medicine. Disease must be cured if possible but after all disease is but the end result of a chain of physiological failures. It is the doctor's duty to prevent those failures if he can. That the complex social and economic structure of our time makes the field a large one is no excuse for a failure to extend the frontiers of medicine to cope with the growing need. The challenge is out and as a profession we accept it. If economic conditions affect food supplies if social changes lead to increased rents if industry uses more intricate solvents we are thereby brought into contact with the basic causes of the problems we have to solve. Medicine as a force on the constructive side of social life has to study the causes of clinical phenomena even if it carries us back through emotional factors to the very roots of peace and war and to the basis of individual and national fitness to survive.

If fitness means anything it means this: the fitting of human beings to fulfil their lives in a manner consistent with the fullest physical and mental development that innate qualities allow.

Further we have to improve those innate qualities. Medicine has become a function of social biology. How can we escape this challenge to the highest effort that has ever been demanded of a single group? We cannot and we do not desire to. In the welter of new forces that are at present impinging on society the doctor can no longer stand aside detached and concerned only with the care of the sick. He has a part to play in the evolution of new systems of living. In the *Supplements* of May 28 and June 4 Dr Karl Haedekamp has given us a glimpse of what the German doctor is doing. Dr Haedekamp remarks that the method must vary according to national characteristics but he has said and implied enough to make us all reconsider our position *vis-à-vis* the State. For us it is a question of whether we will mould the system or allow the system to mould us. In the National Fitness Council this country has a nucleus for a constructive effort which may produce great things and with the creation of a Medical Committee to advise it we hope the ground is now prepared for a drive in the advance of social medicine which could set in motion an urgently needed nation-wide scheme of constructive medicine to cope with the health aspects of the great trek that Western society has now embarked on. As an illustration one of many which could be chosen of the type of new interest medicine must embrace we can take the subject of recreation among the industrial population.

The Industrial Welfare Society has for many years advised employers to help in the creation of sports clubs for their employees. This sounds a simple and useful thing to do but looking through the Society's new booklet<sup>1</sup> one is immediately aware of a new significance possessed by the results of its pioneer work. A channel has been made but water in quite inadequate volume flows down it. The main obstacle is lack of space and equipment for the development of recreational activities by all workers and not merely those employed by the firms who are enlightened or fortunate enough to be able to provide facilities. The multiplicity of interests and the encouragement of small voluntary societies for the pursuit of private ends are healthy both for the community and for the individual. It is to be hoped that this informative and well-thought-out booklet will give added encouragement but when it comes to space and equipment it is surely a job for the National Fitness Council to see that on a basis that all can afford facilities are provided up and down the country so that clubs can keep their identity complete and develop freely with the use of equipment and grounds well laid

<sup>1</sup> *Recreation in Industry: A Guide to Existing Facilities*. Industrial Welfare Society, 1, Hobart Place, Westminster, S.W. 1 (post free).

out and economically maintained on a large scale by the community. In other words, let us have a public service of facilities for healthy recreation in its widest sense. It would be a capital investment yielding a self-supporting return from fees paid by private individuals or by clubs and societies formed within industry. The medical profession struggled hard to create such public utility undertakings as public sanitation and safe water supplies. It operates a vast health insurance scheme. It now reaches out to see whether it cannot enable bodies like the Industrial Welfare Society to increase their usefulness by the creation of self-supporting public undertakings in recreational facilities so designed that schools, universities, industry, and the general public would have the best return from an economically well-managed and well-laid-out series of centres where, among other things, the social mingling of different groups would be facilitated. We would press for Sunday opening, without which the scheme would be futile, and we would encourage all our men to play their games exposed to light and air, so that bronzed backs and pride of carriage should no longer be a Continental virtue.

This is one theme. There are many more. Unless, however, we as a profession are going to use our every endeavour to widen life and enrich health on its social side we shall let our influence slip away, and the rising generations, though they may seek our aid for the relief of pain, will cease to regard us as architects of health. The quack will flourish but true health decay. Moreover, the quest of a security for sound health lies at the root of violent political change. Change is good but violence is retrograde. Let us act in time and use our influence to effect with rapidity those developments which will minister to social welfare and progressive stability.

## NATURE AND NURTURE. THE STUDY OF TWINS

"It is maintained by Helvetius and his set that an infant of genius is quite the same as any other infant, only that certain surprisingly favourable influences accompany him through life especially through childhood, and expand him while others lie close-folded and continue dunces. Herein, say they consists the whole difference between an inspired Prophet and a double-barrelled Game preserver: the inner man of the one has been fostered into generous development, that of the other, crushed down perhaps by vigour of animal digestion and the like has evaded and evaporated or at best sleeps now irresuscitably stagnant at the bottom of his stomach.

With which opinion cries Teutelsdröckh. I should as soon agree as with this other that an acorn might by favourable or unfavourable influences of soil and climate be nursed into a cabbage, or the cabbage seed into an oak. Nevertheless, continues he. I too acknowledge the all but omnipotence of early culture and nurture, thereby we have either a doddering dwarf bush,

or a high-towering, wide shadowing tree, either a sick yellow cabbage, or an edible, luxuriant green one."

In the century since those words were written Francis Galton and his prophet Karl Pearson spread the gospel of Eugenics, of the paramount importance of Nature, which found acceptance among an educated minority and has inspired some legislation. But even those rulers who, like the German dictator, pay the largest legislative tribute to the principle of genetic purity attach the greatest practical importance to early culture and nurture. The accurate delimitation of the parts played by heredity and environment is still an uncompleted task. Drs Newman, Freeman, and Holzinger—a biologist, a psychologist, and a statistician—in a joint study of twins have made a valuable contribution to the subject.<sup>1</sup> The plan of the research which has been the task of ten years was this. In the first place fifty pairs of identical (monozygotic) and fifty pairs of fraternal (dizygotic) twins were to be studied. Here the members of the twin pairs were brought up together, so one could compare different correlates of genetic constitution under common environment. The subjects were physically measured in all appropriate ways and subjected to batteries of tests designed to explore the cognitive and conative sides of the psyche. In the second place, as the result of great pains and expense, nineteen pairs of identical twins were secured who had been separated early in life and brought up under different environmental conditions. These subjects were tested with the same minuteness as those of the first part of the research, and in each case a personal history and photograph are provided.

The results are set out with a wholly admirable modesty and precision. The statistical treatment is clear and not unduly technical, perhaps, even at the cost of lengthening the book, the general reader would have welcomed a full description of the educational and mental tests used, but these are of course available in many textbooks. It would be impossible to summarize adequately the findings in the space at our disposal. Perhaps this sentence from the general conclusions is the best attempt. "We feel in sympathy with Professor H. S. Jennings's dictum that what heredity can do environment can also do." But to leave it at that would create misconception. The evidence of the paramount importance of Nature (if under that term we include pre-natal environmental conditions) in creating differences when pairs under like environment are considered would have gratified such enthusiasts for "Nature" as Karl Pearson himself. From 75 to 90 per cent of the difference variance

<sup>1</sup> *Twins: A Study of Heredity and Environment*. By H. S. Newman, Frank N. Freeman and Karl J. Holzinger. Chicago Press. Cambridge Press. 1935.

is attributable to Nature for physical traits and on the average three quarters of the variance in intelligence also. But the study of separated twins brings out clearly enough the importance of environmental difference particularly in the cognitive aspects of the mind. Intelligence at any rate the manifestation of intelligence is very susceptible to nurture. "From the viewpoint of the educator it is important to note that extreme differences in educational and social environments are accompanied by significant changes in intelligence and educational achievement as measured by our tests." We have some hesitation in quoting isolated passages the authors are extremely careful reasoners and never lose sight of the difficulties of the work. They have risen wholly above the controversial plane on which Nature and nurture, heredity and environment are set in opposition. Indeed Carlyle a century ago or for that matter Francis Galton did not make that mistake.

### TREATMENT OF DISSEMINATED SCLEROSIS

Although disseminated sclerosis has been fully studied over many years in regard to its clinical symptomatology pathology and histology the primary cause and essential nature of the disease remain obscure. From time to time different theories and methods of treatment have been suggested. Their multiplicity indicates all too clearly the insecure scientific foundation upon which they have been built and the baffling nature of the problem. At present attention is focused on Putnam's vascular theory of the disease and this has led to renewed interest in Rovle's method of treatment of the disease by section of the thoracic sympathetic trunk. Wetherell has reported eight cases treated in this manner and in the present issue of this *Journal* Koch and de Savitsch have reported fifteen cases in ten of which varying degrees of improvement resulted from the operation of cervical dorsal sympathectomy. The essential feature in Putnam's theory is that the vascular changes found in the sclerotic plaque—namely the acute thrombi and fibrosis of the vessel walls—are the primary pathological changes giving rise to the characteristic lesion in the surrounding nervous tissue. He bases this on his observation that experimentally produced venous obstruction can give rise to pathological changes very similar to those of disseminated sclerosis. The aetiological factor of the disease therefore lies either in an altered coagulability of the blood or in a local vascular abnormality. It is not by any means accepted that the vascular changes which Putnam has produced experimentally are identical with those of the sclerotic plaque and he has not established the primary significance of the vascular abnormalities. It is doubtful therefore if a sound scientific basis for sympathectomy can be found in Putnam's work and it is not known what effect this operation would have on the venous channels. Apart altogether from Putnam's work sympathectomy

may be beneficial for other reasons and Wetherell rationalizes the procedure on the basis of an improved circulation and decreased sympathetic irritation of the cerebral blood vessels. Chemical factors however probably play a larger part than those of neural origin in the regulation of the cerebral blood vessels so that it is not by any means certain that a large and prolonged increase of blood flow through the sclerotic plaque will result from sympathectomy. This may however be the case but it is clear that this method of treatment must be justified in the present state of our knowledge only by the clinical results obtained and those carrying out the treatment should be very careful in assessing the results. As the operation is one requiring considerable skill and experience it would seem only to be justified by the certainty that considerable improvement in the patient's condition is to be expected. A practical difficulty also arises in that the thoracic and lumbar part of the spinal cord cannot be considered to be denervated as sympathetic fibres are still present along the radicular arteries. It seems clear at all events that patients with disseminated sclerosis can stand such an operative procedure without risk of aggravation of symptoms and the further history of the cases already treated will be awaited with interest.

### AETIOLOGY OF ICTERUS GRAVIS NEONATORUM

The symptomatology and familial association of icterus gravis neonatorum with hydrops foetalis universalis and congenital anaemia and the frequent demonstration of erythroblastosis in these conditions have formed the subject of numerous studies during the past few years. There has been no common agreement as to aetiology. Dr Ruth R. Darrow<sup>1</sup> has now made an extensive survey of the views that have been advanced up to the present time. With regard to the familial association with congenital oedema on the one hand and congenital anaemia on the other it is pointed out that a much more fulminating process is demonstrable pathologically in congenital oedema than in icterus gravis but that there are definite points of similarity. Thus the liver and spleen are likely to be enlarged in both conditions extra-medullary haemopoiesis is commonly seen in both and the placenta which is much enlarged in hydrops is sometimes slightly enlarged in icterus gravis. Similarly there may be localized oedema in cases of icterus gravis and oedema in cases of jaundice and anaemia may occur in either state. In one instance one twin showed oedema and the other developed icterus gravis. In the same way common factors and familial relationships are seen between icterus gravis and congenital anaemia. The author points out that any aetiological explanation must allow for the apparent absence of a hereditary factor that normal children may be born before those affected that the condition is often familial and the parents apparently healthy that the pre natal history seldom provides evidence of significant factors and that any theory of causation must correlate the association of jaundice oedema and anaemia of the

<sup>1</sup> *Arch. Pediat.* 1935 25 373

newborn, the clinical and post-mortem findings, and the erythroblastosis. The explanations advanced may be divided into those primarily implicating the mother and those in which the cause is sought solely within the child. Among the former nutritional disturbance due to defective maternal diet during pregnancy has been advanced to account for congenital anaemia but cannot be held responsible in many cases of icterus gravis, and in the same way maternal disease, particularly syphilis, can be excluded in most recorded cases. Toxaemia of pregnancy has been considered a cause by some authors, but again can only have been operative in a small proportion of cases. The views relating the condition primarily to the foetus are now generally based on the assumption that the jaundice is associated with an excessive destruction of erythrocytes, which is borne out by the observation of increased erythrophagocytosis and haemosiderosis in the liver and spleen. Gierke and others have regarded a primary constitutional anlage defect of the haemopoietic system as the most likely cause. The familial incidence is too large to make a Mendelian recessive character probable. Ruth Darrow considers the various possibilities of toxic action on the liver, and puts forward the hypothesis, as best explaining the facts, that passive sensitization to his own haemoglobin has been transferred to the foetus from the mother, primarily through the placenta during intra-uterine life and subsequently by her milk.

### BIO-ELECTRIC DETECTION OF CANCER

The search for a method of detecting cancer at an early stage never ceases, and efforts have lately been made to identify individuals susceptible to cancer. Recent work in this direction is recorded by Burr, Smith, and Strong<sup>1</sup> with the use of electrical methods the theoretical basis of which is by no means easy to grasp. Over a period of several years Burr has accumulated data from experiments on growth and regeneration in the nervous system, and "by integrating this data with Kappers's theory of neurobiotaxis, Ingvar's galvanotropism, and the studies of A. B. Mathews and E. T. Lund" he and Northrop<sup>2,3</sup> evolved an electrodynamic theory of life according to this all living organisms possess a "steady-state" electrodynamic field, which imposes a characteristic pattern on the development of the organism. On this theory cancer should produce a change in the electrical pattern of the organism, and in the hope of detecting it the potential differences between various points were measured in mice from two of Strong's inbred strains. The axial potentials were higher in the strain which does not develop spontaneous cancer than in the one in which the incidence was high, the differences between the two strains were 10.7 times the probable error. Repeated measurements on young mice of the susceptible strain revealed an increase in the potentials across the chest shortly before tumours were palpable. The increase reached a maximum soon after tumours became palpable and disappeared in two to four weeks. In old mice there

was no anticipatory rise, but a continuous rise from the appearance of the tumours until death, in mice of intermediate ages the results were irregular. The potential differences between tumours and normal tissues were rarely outside normal limits, and the measurements across the chest disclosed an effect of the tumour on the whole organism. Burr and his colleagues are hopeful that the method will eventually serve for the diagnosis of early cancer. It is harmless, and with the necessary machinery could be tested extensively on animals and man. The transitory character of the changes in some animals and the variation of the results with age are evident drawbacks in a diagnostic test. Indeed, when we read that "in general it may be said that in all probability potential differences in the organism are to some extent related to the age of the organism" we are persuaded that the position is not so clear as might appear at first glance.

### JOURNAL OF SOCIAL OPHTHALMOLOGY

The *Journal of Social Ophthalmology* is a new venture of the International Association for the Prevention of Blindness. There is a foreword by Mr. Bishop Harman, who states that blindness is one of the worst, perhaps the worst, of the physical disabilities of humanity. He also points out what an economic disability arises from blindness, both to the sufferer and also to the society or State of which he is a member, both by reason of the cost of the care of the blind person and of the wastage of effective labour. He maintains that it is more economical to spend money on the prevention of blindness than on the care of the blind. There follows a statement of the aims of the new journal by the editor, and an account of the proceeding of the general assembly of the International Association held in Egypt in December, 1937, at the same time as the fifteenth International Ophthalmological Congress. Two subjects were under discussion and are here reported. The first was a national prevention of blindness programme in a tropical country, in which Mr. A. F. MacCallan (Great Britain), Dr. T. Sadek (Egypt), Dr. P. Toulant (N. Africa), Colonel Wright (India), and Professor Wey (Dutch E. Indies) took part. Stress was laid on the need for the effective control of trachoma. The second subject was the social aspect of the prevention of blindness, opened by Dr. Park Lewis of the U.S.A., who said, "Let us unite in fighting the common enemies disease and poverty, and we shall no longer need to build up defences against each other." Dr. P. Baillart of Paris showed what effective service could be got by associating social workers with the ophthalmological clinics established in the hospitals. The new journal is in no sense one of clinical ophthalmology. Its aim makes it an entirely new venture. It is issued with the one purpose of keeping the need for continuous social service before the minds of those upon whom the responsibility for the health of the several countries devolves. The first number is printed in English and French in parallel columns. As occasion suggests other languages may be employed. The journal is sent free to subscribers to the Association, 66, Boulevard Saint-Michel, Paris.

### EFFECT OF OESTRIN ON THE BASAL METABOLIC RATE

The generally beneficial and often spectacular effects of oestrin in the treatment of various menstrual and menopausal disorders have naturally resulted in its almost universal administration in these and allied conditions. With so little experimental evidence as a guide it is natural that dosage should be purely empirical and that there should be the widest variations in the quantities prescribed for the same degree of deficiency. Further though the general tendency of late has been to reduce the dosage to the original rather small amounts, many authorities believe these to be useless and advise the regular injection of quantities of from 10 000 to 1 000 000 units. There is a good deal of evidence for the symptomatic value of these larger doses but the question of possible harmful effects has never yet been satisfactorily settled. The cancerogenic bogey has been fairly completely laid but the possibility of other toxic sequelae remains uncertain. To elucidate this problem Dr. Mary Collett and her co-workers<sup>1</sup> have studied the effect of the therapeutic administration of oestrin on the basal metabolic rate. They found that single intramuscular injections of 1 000 international units caused a fluctuation in the B.M.R. varying from minus 8 to plus 14 per cent. of the original level with a greater and more lasting alteration following consecutive doses. In addition the effects of oral administration persist longer than if equivalent amounts of the hormone are given by injection over a shorter period. These metabolic effects are interesting for while reflex thyroid stimulation has been generally recognized few clinicians have appreciated its possible extent and Dr. Collett's figures serve particularly to emphasize the importance of close metabolic observations when prescribing large doses of oestrin to patients suspected of incipient hyperthyroidism.

### CONTROL OF MALARIA IN HONG KONG

The annual report for 1936 of the Director of Medical and Sanitary Services Hong Kong records an increase in the crude death rate from 22.9 to 26.6 per 1 000. As in previous years respiratory diseases were responsible for some 40 per cent. of the total deaths a state of affairs attributable to overcrowding, poverty and the expectorating habits of the population. It is stated that malaria from which Hong Kong originally derived its reputation for unhealthiness has now practically disappeared from the populous centres of Victoria and Kowloon. As a result of the work of the malariologist and his staff it is now known what species of anophelines exist in the colony where they breed and on what they feed. The colony now possesses all the knowledge necessary to successfully combat malaria. Any particular area can be freed from the menace of mosquitoes and kept free provided there be the power to act, the machinery to carry out the necessary measures and the means to pay the cost. It is stated that the number of deaths attributable to malaria during the year under review was 503 giving a death rate of 0.5

per 1 000. This may be regarded as a remarkably low figure. The report records a severe epidemic of Shiga dysentery. The outbreak started in the month of November when twelve European children developed symptoms so severe that seven of them subsequently died. Within eleven days there were forty-seven cases, all but four being European children under 10 years of age. The only further death however was that of a Chinese infant, the son of a servant employed in a house where two of the original victims of the outbreak had died. Investigation showed that the common causative factor appeared to be a special brand of high-grade milk. Although however the stools of 113 workers were examined no Shiga bacilli were isolated from any of them and it was impossible to incriminate a carrier.

### COMMISSION OF PHARMACOPOEIAL EXPERTS

The Technical Commission of Pharmacopoeial Experts appointed by the Council of the League of Nations at its meeting in January last met at Geneva in May. The Commission's task was to prepare a programme of studies, choose suitable drugs for examination and determine a uniform method of analysis and preparation of the drugs selected. The necessity for such work arises from the difficulties encountered by pharmacists in dispensing prescriptions for travellers from foreign countries and in the replenishment of medicine chests or ships at ports of call. Unification would in addition be of great advantage to manufacturers and would facilitate commerce in drugs between nations. Further it would assist in the comparability of the results of medical treatment in different countries. The Commission prepared a list of the more important drugs which it proposed to study and codify. Draft schemes for the preparation of monographs on the drugs were agreed upon and a number of general principles were settled. The list of drugs was divided amongst the members of the Commission for the purpose of study in collaboration with experts in their own countries.

### PROFESSOR FREUD IN ENGLAND

Professor Sigmund Freud accompanied by his wife and other members of his family arrived in London on June 6 from Vienna having travelled overnight from Paris. The Home Office has given him an unrestricted permit to live in this country and he has taken up residence in a house in Elsworthy Road, Hampstead. Professor Freud whose eighty-second birthday was on May 6 is visiting England for the first time for sixty-two years. His intention is to spend the remainder of his days here in study and research. The new German authorities in Austria have consented to allow his library and personal effects to be sent after him, but his publishing house in Vienna has been closed. Dr. Anna Freud on behalf of her father has denied rumours that he or any members of his family were under arrest in Vienna. The medical profession of Great Britain will feel proud that their country has offered an asylum to Professor Freud and that he has chosen it as his new home.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## TONSILLECTOMY

BY

LIONEL COLLEDGE, F.R.C.S.

The indications for tonsillectomy present a problem of daily occurrence varying widely with individual patients, and in practice we must sometimes depart from general rules laid down in academic discussions. Once the question of tonsillectomy has been raised in a particular case there is a tendency towards the view that it can do no harm and always does good by freeing the patient from a focus of sepsis, either actual or potential, and from attacks of tonsillitis, and therefore the sooner the operation is done the better. This doctrine may apply to many patients, but it is far from true in relation to children, to whom it has often been ruthlessly applied. A certain vagueness and difference of opinion on this point is inevitable in the absence of an exact knowledge of the physiology and functional activity of the tonsil in childhood, although various unproved theories have been advanced, but clinical study provides some practical information.

### When to Perform Tonsillectomy

Frequently, if not normally, the tonsils in the early years of childhood become enlarged, and this enlargement has been regarded as an indication, with more right as a justification, for removing them. It should in fact be considered primarily as an indication for preserving them, unless the enlargement is so great as to produce mechanically obstructive symptoms, which is quite rare. The nature of the needs in response to which the enlargement occurs is unknown, but these needs are probably nutritional or arise from some defect in nutrition, which will be revealed by research, for it is much commoner in children brought up in poor circumstances than in those for whom an abundant supply of suitable food, fresh air, and light is available. If this hypothesis is correct tonsillar enlargement in early childhood is compensatory in character, and should be treated by improvement in hygiene rather than by extirpation, and this view has the practical support of the observation that recurrence by enlargement of the lingual tonsil and adenoid tissue in the nasopharynx is a common post-operative sequel. It is therefore wise, unless urgent indications are present—and this is rare—to defer any operation until at least the age of 5 and preferably until 7 or even later. It must also be made clear what advantage the child gains if the operation is performed between the ages of 4 and 10 years. Kaiser studied this question in two large groups of children, using one as a control.

Two groups, each comprising 2,200 children, were observed over a period of ten years. In one group the operation of tonsillectomy was performed, and in the other it was recommended but not performed. The benefits obtained in the first three years became less conspicuous in later years, so that the clinical condition of the members in the two groups became more alike. Thus the immediate freedom from sore throats was not maintained and seven years later 10 per cent in the first group were found to be still subject to them. The incidence of rheumatic fever proved to be 33 per cent less in those

children whose tonsils had been removed, but the operation has no influence in preventing recurrent attacks of rheumatism when performed after the initial attack. It does not protect against rheumatic carditis, nor does it affect the incidence of chorea. It gives some slight protection against scarlet fever, but reduces its incidence by less than 50 per cent. The influence of tonsillectomy on the incidence of diphtheria is more pronounced. Consequently, in recommending the operation on relative indications certain benefits to the child may be legitimately claimed, but these can be easily exaggerated.

Frequently recurring sore throats and enlargement of the cervical lymphatic glands are absolute indications for tonsillectomy in children. Nasal obstruction and otorrhoea in the absence of caries of the middle ear are indications for the removal of adenoids but not necessarily of tonsils, and in small children preservation of the latter is the best guarantee against recurrence of adenoids. In bigger children, in whom the physiological need for lymphoid tissue is diminishing, it is customary to combine the two operations, and this usually gives a satisfactory result without great risk of recurrence.

In older persons the tonsils may be removed on account of recurrent sore throats or quinsies, on account of persistent enlargement or infection in a tonsil which has been the site of tonsillitis, or to eliminate a source of focal sepsis which is causing remote symptoms such as rheumatism, arthritis, neuritis, iritis, cardiac irregularities, and digestive disorders. In the first group the indication is an absolute one provided that no general contraindication to surgical intervention is present, in the second group the indication is relative, and a reasonable connexion must be established before recommending tonsillectomy, but in well-chosen cases the elimination of a septic focus has a strikingly beneficial effect on a remote lesion. The age of the patient is not of much consequence provided that definite indications are present, and tonsillectomy is sometimes of great benefit to old people, but in the absence of clearly defined indications the result is apt to be disappointing in elderly persons.

Before recommending tonsillectomy for focal sepsis it is necessary to demonstrate that the tonsils are grossly infected, and this is not always quite simple, because in such cases the tonsils are often small, are concealed by the faucial pillars, and at first glance may appear to be absent. Two small tongue depressors should be used, with one of these the back of the tongue is depressed, and with the other the anterior pillar is pressed aside, exposing the underlying tonsil. By this manoeuvre a gush of sour foul smelling pus can often be expressed from the crypta magna or supratonsillar fossa. A crimson patch on the anterior pillar is an indication of this condition underneath.

### Technique

In the matter of technique a variety of different opinions and details of procedure are current in the operation for removal of the tonsils. In children it may be done with the guillotine or by dissection, but it is a good general rule not to use the guillotine after the age of 15 and many surgeons now prefer the operation by dissection for patients of all ages. The soft friable tonsils, which tear readily, are more easily removed with the guillotine than

by dissection. The guillotine method has also the advantage of rapidity but some practice is necessary to acquire sufficient dexterity. Compared with the dissection method however it has the disadvantage that the deep surface of the tonsil not always being smooth an outlying part projecting through the capsule may be shaved off and remain in the tonsil bed and again occasionally a vein in the tonsil bed is buttonholed and being unable to retract continues to bleed through the lateral opening. The portions of tonsil are sometimes left behind after the guillotine operation if not skilfully performed is insufficient ground to condemn it because the same thing may occur after dissection.

Whichever method is employed the aim of the operator should be to remove the whole tonsil without injury to the faucial pillars or to the palate. Healing then takes

FIG 1

FIG 2

place with the minimum of scar tissue—and distortion. If the uvula is accidentally included in the ring of the guillotine or the pillars are torn during dissection gross deformity of the fauces and soft palate may be produced.

#### Enucleation by the Guillotine

The operation can be performed under a short anaesthetic with ethyl chloride but a more deliberate procedure under ether is preferable. The patient lies on the back with the shoulder slightly raised on a low pillow or a folded towel. The anaesthetist stands at the head of the table and the operator on the right hand side of the patient. The mouth is opened with a Doven's gag but not so widely as to stretch the pillars of the fauces. The tongue is depressed and the ring of the guillotine passed under the lower pole of the right tonsil with the handle of the instrument pointing to the left of the patient

(Fig. 1). The hand is now depressed so that the tonsil is forced forward by the instrument on to the alveolar eminence of the mandible (Fig. 2). This eminence is formed by the projection of the last molar tooth at the end of the mandibular ridge. The handle of the instrument now lies across the left cheek of the patient. The left forefinger is then removed from the corner of the mouth and pressed against the anterior faucial pillar so that the entire tonsil is gently pushed through the ring of the guillotine (Fig. 3). The tonsil can be felt to slip through the ring and the blade is then closed by the thumb of the right hand with the cutting edge between the anterior pillar and the tonsil. The hand is now pronated and the tonsil lifted out held on the lower surface of the guillotine (Fig. 4). To remove the left tonsil the hands must be used in the reverse way. The guillotine being held in the left hand or alternatively the operator must move to the head of the table and stand behind the patient. In this way the tonsil is removed complete, including the supratoronsillar fossa.

The smallest guillotine which will allow the entire tonsil to pass through the ring should be used, and the blade

FIG 3

FIG 4

should be slightly blunted so that it will follow the line between the capsule of the tonsil and the side of the pharynx without cutting into the substance of the tonsil. The blade also crushes the blood vessels supplying the tonsil but must not be too blunt otherwise that organ is torn out of its bed instead of being cut away.

#### Enucleation by Dissection

For the operation by dissection either a local or a general anaesthetic may be used but the former is only suitable for adults. For local anaesthesia the patient is placed in the sitting position and a little 5 per cent cocaine is applied to the fauces. An injection of 2 per cent novocain with 1 in 10,000 adrenaline is then made with a long needle in five spots in the fauces around each tonsil—one above two behind and two in front. If general anaesthesia is employed the patient is usually

placed on the back with the head well extended, so that blood runs down into the nasopharynx. The mouth is opened with a Doyen gag and the tongue drawn forward, or a Davis gag which holds down the back of the tongue

FIG 5

and at the same time draws it forward, may be used (Fig 5). The latter gag is popular and is much employed, but it is complicated and easily put out of order, and is not necessary. It is quite as satisfactory to use the position recommended by Butlin, in which the patient is turned on to the right shoulder. With the mouth gagged

even for a nervous subject. Simple general anaesthesia by inhalation and insufflation is the safest and most satisfactory method. The operator either sits at the head of the table or stands on the right-hand side, according to the patient's position, and he should wear a head-light. The tonsil is seized with forceps and the mucous membrane divided at its reflection from the anterior pillar or to the tonsil. The mucous membrane is thus divided well behind the free edge of the pillar, which is kept covered with an intact surface of mucous membrane. This opening can be made with the point of a knife or closed fine dissecting forceps, and the white smooth capsule of the tonsil is exposed, showing that the dissection is proceeding in the right layer (Fig 6). If there has been a previous operation the tonsil is often surrounded by an annular scar, and the anterior pillar must be picked up and the incision made underneath it to expose the capsule before the tonsil can be grasped. This is a satisfactory routine method of beginning the dissection. By blunt dissection close to the capsule with long-handled scissors and dissecting forceps the tonsil is then shelled out of its bed, the mucous membrane being divided all round the periphery (Fig 7). The lower pole is often well defined, but in many cases it merges into the lingual tonsil and must be divided with scissors (Fig 8)—a more satisfactory method than the use of a snare, as the division can be made with greater precision, without the risk of leaving a part of the lower pole behind. The tonsil is not in direct relation to the superior constrictor of the pharynx, but is separated from it by the palatopharyngeus. This muscle spreads out, sending a slip that is attached to the capsule of the tonsil just below the middle, and accounts for the frequency with which muscle fibres are found on the capsule of excised tonsils.

The blood vessels torn across by the blunt dissection stop bleeding quickly as a rule if gauze swabs are applied, or, if this fails, pledgets of cotton-wool often succeed. Any persistent bleeding usually comes from a vessel about the middle of the tonsil bed, less commonly at the lower end near the tongue.

FIG 6

FIG 7

FIG 8

open and the tongue drawn forwards, blood collects in the cheek and runs out of the corner of the mouth.

Intratracheal anaesthesia with gas-oxygen and ether is often employed, but it causes increased bleeding, though it has the advantage that the entrance to the larynx can be packed off round the intratracheal tube. Preliminary medication with avertin, paraldehyde or barbiturate compounds is also often used with the object of allaying the apprehensions of the patient, but much post-operative anxiety is thus caused and it lacks any real justification.

Many instruments have been devised to apply ligatures to bleeding-points. The simplest and most certain method is to pick up the bleeding vessel with long forceps and to under-run and tie it with a silk ligature on a Reverdin needle. This leaves the faucial pillars quite intact. In the few cases where this fails the Reverdin needle can be used to transfix and suture the pillars together with silk threads. This obliterates the raw tonsil bed, but it causes scarring and the sutures should be divided on the following day.

If reactionary haemorrhage occurs within the first two hours and does not cease very quickly it is better to give the patient a second anæsthetic and secure the bleeding point. Secondary haemorrhage occasionally appears about the sixth day after the operation when the slough which forms over the raw surface separates. This seldom causes any serious trouble but to avoid it the patient should remain quiet wherever the operation is done until the seventh or eighth day.

#### Adenoids

When adenoids require removal at the same operation it is usual to do this after the tonsillectomy has been completed. The palate is drawn forwards with a finger or with a palate retractor, the adenoid curette is inserted into the nasopharynx until the beak touches the vomer and is then swept firmly round following the curve of the nasopharyngeal vault. After the operation the patient should be watched carefully for any reactionary bleeding as this may be concealed if the blood is swallowed instead of ejected. Powdered aspirin or aspirin gargle usually suffices to relieve pain but for adults an injection of morphine is permissible on the evening after the operation. Cold soft food may be taken the following day. Ice cream is welcomed by children. A purge is usually indicated within the first forty-eight hours to rid the bowel of swallowed blood. Castor oil is suitable but salines should be avoided as they are very painful to swallow.

#### After-treatment

A rare but tiresome complication is temporary paresis of the soft palate due to infiltration and swelling of the muscles. This causes difficulty in swallowing and regurgitation particularly of fluids through the nose which may last for about ten days. Some additional care is then necessary in the choice of suitable soft food such as scrambled eggs, porridge with cream or mashed potatoes, meat, toast, biscuits and cheese are particularly difficult to swallow in this condition and are accordingly to be avoided. The difficulty in taking fluid may be overcome to some extent by suction through a tube or a straw.

## ANTI-VENEREAL MEASURES IN SCANDINAVIA

### COMMISSION'S REPORT

Should venereal disease be dealt with compulsorily in this country or not? This question was raised before the Trevethin Committee in 1923 in Parliament by the Edinburgh Corporation in 1928 and on a number of other occasions by various bodies and individuals. Many arguments have been put forward for and against such a policy and with a view to obtaining some definite evidence of its value or otherwise the British Social Hygiene Council in June 1936 urged the Minister of Health to send a commission of experts to Denmark, Sweden, Norway and Holland to study conditions in these countries. The commission which consisted of Colonel L. W. Harrison and Mr. Dudley C. L. Ward of the Ministry of Health, Dr. T. Ferguson of the Department of Health for Scotland and Dr. Margaret Rorke of the Royal Free Hospital, London has just issued its report.\*

#### For and Against Compulsion

Before considering this report it may be instructive to consider some of the arguments which have been advanced

\* *Venereal Measures in Certain Scandinavian Countries*, 1st and 2nd Reports on Public Health and Medical Subjects No. 83, H.M. Stationery Office (2s. 6d.). A general article on the Commission's visit to Scandinavia appeared in the *Journal* of June 4.

for and against a policy of compulsory treatment. Those in favour of such a policy point out that (1) many persons infected with venereal disease in a contagious form never come under medical care and thereby spread infection (these are chiefly women); (2) large numbers of patients at V.D. clinics default before they have completed treatment and/or become non-contagious; and (3) parents frequently fail through ignorance or unwillingness to have their congenitally syphilitic children treated adequately and therefore prejudice their chances of growing up to become healthy and useful citizens.

Those against point out that compulsory measures (1) may induce the infected to conceal their disease from fear of exposure; (2) are not easy to apply in such a densely populated country as this on account of the difficulty of tracing those who try to avoid the law; (3) may open the way to blackmail; and (4) are not consistent with the British idea of the liberty of the subject.

The Trevethin Committee appear to have considered compulsory measures impracticable and inadvisable and the Edinburgh Corporation Bill was defeated in the House of Commons on its second reading by 126 votes to 93 so that it would seem that general opinion in this country is against compulsory treatment. On the other hand there are those who point to the remarkably low incidence of syphilis in three countries which have adopted compulsion in order to form an opinion as to how far conditions are comparable between the countries mentioned and Great Britain it may be useful to consider each country in turn.

#### Denmark

Denmark has an area of 16,575 square miles and a population of 2,664,919 giving a density of 224 per square mile which is about one-third of that of England and Wales. Copenhagen has a population of 666,269 and of the eight and nine provincial towns only two have a population of more than 10,000, nine even having less than 10,000. The population is the more rural than in this country but ports are numerous and communication by sea very free, the former is admitted to lead to a low incidence of venereal disease while the latter allows of its importation.

The standard of education and intelligence of the population are high and public health administration is advanced. Medical education is thorough and occupies a minimum of seven years; a specialist has to spend several years more studying his own and other subjects. The result is that the medical profession has a very high standing and patients attach much weight to the opinions of their doctors.

Legislation for the control of venereal diseases dates back to 1874 and at the present time the law of 1906 is in force. Under this every person suffering from a venereal disease is entitled to free treatment but is obliged to submit to it, concealment and conveying of infection are punishable by imprisonment up to four years; doctors must make a return of their cases, though notification of individual cases is not necessary; a defaulter may be punished and compelled to attend for treatment if necessary by the police; a certificate of freedom from venereal disease is required for marriage and if either party at the time of consummation was suffering from a venereal disease in a communicable form a judicial separation or a divorce may be obtained.

#### TREATMENT AND INCIDENCE

Free treatment is available for all; there are seven centres in Copenhagen and in most other places treatment is carried out by district health offices or specially authorized local practitioners. Ample bed accommodation is provided. The cost is about one million kroner per annum. Serum tests for the whole country are carried out at the State Serum Institute and by this means there has been established a unique institution for the statistical study of syphilitic infection. Some 110,000 blood samples are received each year.

It is considered that very few persons evade the law or compulsory treatment. The police have rarely to be called

† About 2-4% per annum.

in and false certificates by unscrupulous doctors are almost unknown

The incidence of venereal disease is not easy to ascertain—though it is well known that there has been a substantial reduction during recent years—owing to the fact that reports do not distinguish between fresh and old infections. After reviewing all the facts the commission came to the conclusion that in 1936 new infections with syphilis were about 600 per annum or 1.6 per 10,000 of the population for the whole country and about 6 per 10,000 for Copenhagen alone. These figures may be compared with 14 and 52 in 1919, and 7 and 26 in 1926. There has been no comparable reduction in the incidence of gonorrhoea: the rate for Copenhagen fell from 119 in 1919 to 76 in 1936 while for the whole country the rates were 48 and 28 respectively. On the other hand the rate for the whole country was approximately the same in 1936 as it was in 1906 though during this period it had fallen from 112 to 76 in Copenhagen alone.

### Sweden

Sweden has an area of 173,547 square miles and a population of 6,249,489, with a density of 39.5 per square mile—about one eighteenth of that of England and Wales. There are only forty towns with a population over 10,000 but sea communications are very free. Standards of education, both lay and medical are high and comparable with those of Denmark.

In the eighteenth century the west coast was one of the principal sources of venereal infection and since 1787 various measures have been drafted to combat this. In January 1919 the *lex venenis* came into force. This makes treatment compulsory till the patient is non-infectious; free treatment is available for all cases must be reported but not by name; transmission of infection is punishable by imprisonment; marriage certificates are necessary; defaulters are reported, sought out and if necessary compulsorily removed to hospital; and the treatment of venereal disease by unqualified persons is prohibited. Treatment facilities are available in polyclinics in all towns with a population of 20,000 or over; in the country treatment is carried out by municipal and rural district medical officers employed by the State. The cost is about 500,000 kronor per annum.

The Swede is very amenable to the law and few patients require coercion. It is computed that less than 10 per cent of cases have to be reported as defaulters and of these only 20 to 25 per cent cannot be traced though on the other hand a considerable proportion of sources of infection (in 1934 107 out of 175) cannot be found. The incidence of syphilis in all Sweden was 10.2 per 10,000 in 1919, 1.2 in 1925 and 0.67 in 1935; the corresponding rates for Stockholm being 44.46 and 1.8 respectively. As regards gonorrhoea in Stockholm the maximum of 203.7 per 10,000 in 1918 fell to half this figure in 1922 and to 65.0 in 1935; for the whole country the figures were 28.18 and 1.8 respectively.

### Norway

Norway has an area of 124,588 square miles and a population of 2,881,514 with a density of about 23 per square mile; about 69 per cent of the population is rural. Oslo (253,124) is the only town with a population over 100,000, and there are eighteen principal towns. Communication by sea is very free but otherwise geographical and social conditions favour a low incidence of venereal disease. Education is of the same high standard as in Denmark and Sweden.

As regards legislation venereal diseases are dealt with under the laws relating to all infectious diseases principally those of 1860 and 1927. Under these a doctor must report cases to the local health officer and furnish a summary of all cases every year and patients suffering from a venereal disease must submit to treatment in hospital if required to do so. Licensed houses were abolished in 1880. Persons knowing themselves to be suffering from a contagious disease render themselves liable to imprisonment if they expose others to infection and it is illegal to place a syphilitic child under the care of another

person, or to enter a household as domestic servant in similar circumstances. Marriage is also barred whilst a person is contagious. Further measures were contemplated in 1923, such as free examination and treatment, compulsory treatment, and compulsory notification, all at the expense of the State but these were not adopted however merchant seamen are treated free, and free arsphenamine is to be supplied.

Under present conditions indigent persons may obtain free treatment, and syphilis and gonorrhoea come within the scope of the compulsory health insurance scheme otherwise the patient must bear the cost. The peak of the incidence of syphilis in Oslo occurred in 1919, when the rate was 36.2 per 10,000, this fell to 19.5 in 1926 and to 7.5 in 1935 though it was only half this in 1934, for the whole country the figures were 6.6 in 1919, 3.7 in 1926, and 1.6 in 1935. As regards gonorrhoea Oslo showed a rate of 77 per 10,000 population in 1919 rising to over 110 in 1927 and falling to 67 in 1935; the corresponding rates for all Norway were 22, 25, and 19 respectively.

### Holland

Holland has an area of 12,692 square miles and a population of 8,474,506, giving a density of 667.7 per square mile. It has three towns with populations of over 400,000 and sixteen other large towns. It is therefore much more densely populated than Denmark, Norway, or Sweden, and this fact together with its heavy traffic by sea or river would be expected to render it more vulnerable to venereal infection. The standard of general education is high and the medical curriculum lasts for a minimum of seven years. The arrangements for the control of venereal disease depend largely on voluntary effort, free treatment except for merchant seamen is not provided, there is no notification or compulsory treatment and prostitution is not State regulated. A system of social service has, however, been set up in nine of the eleven provinces under the auspices of the Green Cross, White Cross, and White-Yellow Cross Societies subsidized to some extent by the Ministry of Health. In the circumstances no statistics are available but some figures have been collected relating to the year 1935. The incidence of syphilis is stated to be 1.06 and of gonorrhoea 5.6 per 10,000 of population; the former figure is probably near the mark, but the latter too low.

### Conclusion

The Commission found that, in general, compulsory measures do not meet with serious opposition, the general public is co-operative, and extreme measures are seldom necessary. In the Scandinavian countries certain factors prevail which make for the smooth working of anti-venereal disease measures. These are briefly (1) homogeneous populations, (2) a high sense of communal responsibility, (3) implicit trust in a highly trained medical profession largely State-paid, (4) uniformity of medical practice, and (5) the venereal diseases are not looked upon as shameful. Notification appears to be efficient in Sweden, incomplete in Denmark and even more so in Norway.

The effects of anti-venereal measures on fresh syphilis have been very great in both Denmark and Sweden where treatment is compulsory, but the fact that in Holland and England and Wales, where reliance is placed mainly on persuasion, they have been almost equally successful makes it doubtful whether this is due directly to compulsion. As regards fresh gonorrhoea the same seems to hold, since Sweden and Denmark, where compulsory treatment is in force, show rates of 17.9 and 27 per 10,000 as against 8.7 for England and Wales and 5.6 for Holland where treatment is voluntary, even though the last two figures are probably on the low side.

As a result of its inquiries the Commission came to the conclusion that compulsion did not lead to the control of disease in Denmark and Sweden, mainly on account of national characteristics; on the other hand Holland and England and Wales were able to show almost equally good results in reducing the incidence of syphilis.

None of the five countries can point to any great success in reducing the incidence of gonorrhoea and the explanation for this is not altogether clear. It would appear that syphilis is more easily and more quickly rendered non-contagious while it is probable that the general public regards it as a much more serious disease than gonorrhoea and therefore is more inquisitive to secure treatment.

The main desiderata for an anti-venereal diseases campaign therefore appear to be adequate facilities for free treatment for all an enlightened law abiding public and the removal of the odium attached to these diseases. The comparative failure in the campaign against gonorrhoea suggests that much more research—and the necessary funds for carrying this out—is required before a reduction comparable with that in syphilis is likely to be obtained though treatment by sulphanilamide holds out some hope of success.

## NATIONAL INSURANCE IN AUSTRALIA

Last week the Australian House of Representatives passed the second reading of a Bill for an Act to provide for insurance against certain contingencies affecting employees and the wives, children, widows and orphans of employees and for other purposes. The complete text of the Bill has only now come to hand in England and its provisions are described in the present article. In the course of the debate in the House of Representatives the Australian Government announced that it was prepared to make some extensions of the Bill, and made certain statements as to its action thereunder. The most important of these will be given after the proposals as set out in the Bill have been described but any comment upon these and other controversial points and upon the reaction to these proposals of the medical profession in Australia may be more conveniently reserved until fuller details have reached this country.

### Scope of the Bill

The Bill deals both with national health insurance and with pensions. It does not touch the subject of unemployment insurance but Mr Lyons the Prime Minister announced that a measure with regard to this would be introduced though he could not say at what date this would be. On the other two matters it is known that the Federal Government has been making wide and careful inquiry for at least two years past and that it has had very material help in such inquiry from the Ministry of Health in London. It is not surprising therefore, to find that the provisions of the Bill in general follow with some closeness those embodied in similar legislation in Great Britain nor that the Bill is a long and complicated one and contains a number of clauses of exact significance of which it is not easy to determine and which indeed, must be largely conditioned by the terms of rules and regulations that will be made hereafter. There are 188 sections and four schedules.

After an important clause of definitions the Bill provides that there shall be set up a National Insurance Commission consisting of three commissioners appointed by the Governor General but there is to be a deputy commissioner for each State who shall have such powers and functions as the Commission directs. Moreover, the Commission may delegate any of its powers and functions in relation to any matters or class of matters or to any particular State or part of the Commonwealth so that the delegated powers and functions may be exercised by the delegate with reference to the matters or class of matters specified or the State or part of the Commonwealth specified in the instrument of delegation. These powers of delegation and the functions assigned to a deputy commissioner are very important for the respective spheres of the Commonwealth and of the several States may possibly give rise to difficulty or dispute. It is understood that the States have control of health legisla-

tion and administration within their own areas, and that it is only because the present Bill is regarded as insurance legislation that it becomes a Federal matter. In such a wide and intricate service as is proposed the spirit in which it is administered and its general uniformity of administration are of the first importance and it is possible that the subsection which says that every delegation by the Commission shall be revocable in writing at will may not prove unnecessary.

Aboriginal natives of Australia or of the Pacific Islands are not included in the scheme at all. The persons to be insured are of four classes: (1) all employed persons (with certain exceptions on much the same lines as in Great Britain) between the age of 16 years and the age of 65 for men and 60 for women; (2) voluntary contributors below these maximum ages who have been insured as employed contributors for two years and who have ceased to be employed; (3) juvenile contributors employed persons between 14 and 16 years of age, insured for medical benefit only; (4) special voluntary contributors married women previously insured for not less than five years who may elect to contribute for old age pension only. Except for this special provision, a married woman who is not insured by virtue of her own insurable employment does not come within the scheme at all. With regard to medical benefit a voluntary contributor whose total income from all sources exceeds £365 a year is not entitled thereto. On the other hand an insured person who is so entitled and who attains the maximum age or becomes entitled to receive an old age pension remains entitled to medical benefit during the remainder of his life. Persons employed otherwise than by way of manual labour whose rate of remuneration exceeds £365 a year are not included as insured persons.

### Payment of Contributions

The amounts of the weekly contributions to be paid are as follows: (1) By and in respect of employed contributors and by voluntary contributors entitled to medical benefit—1s 3d in respect of health insurance and 1s 9d for the pensions fund for males 1s 2d and 10d respectively for females. (2) By voluntary contributors not entitled to medical benefit males 11d and 1s 9d females, 10d and 10d. (3) Special voluntary contributors 1s. All voluntary contributors pay themselves the whole of the contribution. Employers pay a portion of the contribution in respect of their employees but the proportion imposed upon them is not stated, nor is the amount to be paid by and in respect of juvenile contributors stated but the whole of this contribution goes to the Health Insurance Fund. Presumably these unspecified amounts are to be determined from time to time under a section which states: Contributions at the rates declared by the Parliament shall be levied and paid by the persons by whom the contributions are so declared to be payable. The employer is made responsible for paying the contribution in the first instance but he may recover the employee's share by deduction from his wages or other remuneration. The rates of contribution of voluntary contributors are to be increased by sixpence a week after five years and by a further sixpence in the case of males only after a further five years—that is, from the year 1949. The method of payment is by stamps affixed to cards or books or in such other manner as is prescribed.

The benefits are enumerated thus: medical sickness, disablement additional old age pension widows pensions orphan's pension, dependent child's allowance. There is an important provision that where the Commission has certified that on account of remoteness or any other circumstance related to the locality or nature of any employment the effective administration of any benefits which are specified in the certificate is impracticable the insurance shall be only for benefits other than those specified. Provision is also made for certain free insurance periods corresponding to those in the system in Great Britain.

### Medical Benefit

Medical benefit is defined in almost the exact terms of the English Acts. It comprises general medical practitioner and pharmacist services only, and includes certification. The Commission will make arrangements and enter into contracts or agreements for these services, and regional medical lists will be published. Every registered medical practitioner has the right to have his name included and there is to be free choice by both doctor and patient within the usual limits. However, if the Commission is satisfied that in any State or district such an arrangement is unsatisfactory or inadequate it may make such other arrangement for the supply of the services as it thinks fit. There is to be set up a central medical benefit council consisting of persons representing medical practitioners, pharmacists, employers, and insured persons, and others selected by the Minister in charge of the service. This council is to give advice to the Commission with respect to any matter relating to medical benefit referred to it and will have such other powers and duties as are prescribed. District medical benefit committees are also to be established, with such powers and duties in relation to complaints by insured persons, medical practitioners, pharmaceutical chemists, and approved societies in connexion with medical benefit in the district for which it is appointed as may be prescribed by regulations. If representative committees of medical practitioners and of pharmacists respectively are constituted they may be recognized by the Commission and appropriately used. Any relevant representations made by such committees must be considered by the Commission.

### Cash Benefits and Finance

With regard to the cash benefits, to be administered mainly by approved societies as in Great Britain, the weekly rates of pay are thus set out: (1) Sickness benefit: (a) adults and married minors, males 20s, females 15s, (b) unmarried minors insured for two years, males 15s, females 12s 6d, (c) unmarried minors insured for a less period, males 12s, females 10s. (2) Disablement benefit: (a) adults and married minors, males 15s, females 12s 6d, (b) unmarried minors, males 12s, females 10s. (3) Old age pension: males 20s, females 15s. (4) Widow's pension 12s 6d, later 15s. (5) Orphan's pension 7s 6d. (6) Dependent child's allowance 3s 6d. Sickness benefit, however, commences only on the seventh day of incapacity and not until six months after entry into insurance. The incidental provisions regarding sickness and disablement benefits are much the same as in the English Acts. Additional benefits too are defined as in those Acts. The old age pension begins at the maximum age for insurance—males 65 years, females 60 years. There are a considerable number of clauses safeguarding these various pensions or allowances in appropriate ways.

Part VI of the Bill deals with central finance and Part VII with the constitution, conduct and finance of approved societies. Part VIII contains miscellaneous provisions relating mainly to legal matters regarding disputes, offences, and penalties. There is to be a Board of Trustees for national insurance funds consisting of the chairman of the Commission (who is to be the chairman of the Board), the Solicitor General of the Commonwealth, the Secretary to the Treasury, the Governor of the Commonwealth Bank of Australia, the Commonwealth Statistician, and the Commonwealth Actuary. The Health Insurance Fund and the Pensions Insurance Fund are to be kept separate, and the Medical Benefit Account is to be kept separately within the former. It is to be constituted at the rate of 10s in respect of males and 17s 6d in respect of females for the total number of persons insured in respect thereto. The Government payments to the National Insurance Trust account are to be as follows: (a) an annual amount of £100,000 to the cost of the Commission in the administration of health benefits, (b) an amount of 10s per member to approved societies (other than juveniles) in

respect of reserve values till these are extinguished, (c) an annual amount of one million pounds for the first five years thereafter rising by half a million each year till it reaches a maximum of ten millions, then continuing each year at this maximum.

### Medical Capitation Fee

It is understood that on matters relating to medical benefit the Commonwealth Government has been in negotiation with the Federal Council of the British Medical Association, and that the capitation fee suggested for medical practitioners who enter the service is 11s. This has not been accepted by the profession, and further information is awaited. The two most important statements made on behalf of the Government in the course of the debate in the House of Representatives have been reported thus: (1) medical benefit may be extended to the dependants of "insured males who have voluntarily contributed to existing benefit organizations which will be subsidized by the Government. More than 700,000 families are affected", and (2) there is no intention of "appointing doctors to permanent positions under the Bill if the profession declined to work the scheme on account of disagreement about the capitation fee. Both these statements await elucidation.

## Reports of Societies

### PLACENTAL INFECTION IN MALARIA

A meeting of the Royal Society of Tropical Medicine and Hygiene was held on May 19 at Manson House, Portland Place. Lieutenant-Colonel S. P. JAMES was in the chair and Dr P. C. C. GARNHAM read a paper on the placenta in malaria, with special reference to reticulo-endothelial immunity.

Dr Garnham said that a fruitful line of study in present-day malariology was undoubtedly the determination of the process whereby the indigenous inhabitant of a malarial country overcame his infection. The reticulo-endothelium constituted the chief weapon of defence, and hitherto, in man, the study of this system had been largely undertaken in fatal cases of the disease. The placenta appeared to offer much greater facilities for detailed observations, and by the examination of over 500 placentas all phases of the disease had been carefully studied. The placenta, too, was unique, in that in its intervillous spaces parasites and reticulo-endothelial cells alone were present and the inter-reaction of the two could be easily observed.

The well-known picture of schizonts, phagocytes, etc., was found to be absent in the youngest placenta in malaria and to occur only after the fourth month of pregnancy, it was present only in subtertian infections and was absent in quartan. Examination of placenta obtained from cases in different phases of the disease revealed that at the beginning of a new infection no reticulo-endothelial cells were present though schizonts were extremely numerous. The placenta of a patient who had had malaria for a week showed however, a marked reticulo-endothelial response. In relapses, on the other hand many reticulo-endothelial cells were found practically from the start, presumably because there was a sensitized apparatus still extant from the original attack. In cerebral malaria there was, surprisingly enough, no intrinsic failure of the cellular mechanism. In chronic malaria the intervillous spaces were occupied almost entirely by myriads of reticulo-endothelial cells and lymphocytes. All stages in the transformation of lymphocytes into the former cells by way of the polyblast of Maximow were seen and there was little doubt that this represented their mode of origin. This finding, in human beings corroborated the recent work of T. H. Stæffer, Cannon and Mulligan on the derivation of the splenic macrophages in bird and monkey malaria.

### Origin of Placental Phagocytes

The possibility of an origin for the placental phagocytes from local fixed cells was excluded (a) on histological evidence and (b) as the result of *intra vitam* trypan blue experiments. This dye was absorbed only by the fixed histiocytes and none was ever present in the macrophages. Other authors had shown the remarkable lack of affinity for trypan blue of the monocytes of the spleen. For this reason it was suggested that certain blockade experiments in malaria had been wrongly interpreted based as they were upon the assumption that trypan blue was absorbed by the malarial macrophage. Trypan blue was shown to have a beneficial effect in chronic malaria. A remarkable feature was the periodicity of its excretion in the urine, a periodicity lasting for weeks and occupying the hours from about 5 a.m. to noon each day.

To see if congenital malaria occurred 404 cases were examined. A quarter of these showed positive placental films. The blood of the infants was examined at birth and after seven days, always with negative results. It must not be forgotten that these cases came from hyper-endemic areas where immunity was high and acute malignant infections rare.

### Immunity and Cellular Changes

Major H. W. MULLIGAN in opening the discussion said considerable advances in our knowledge of the immunology of malaria had resulted from the study of experimental avian and simian malaria and of malaria induced for therapeutic purposes in general paralysis of the insane. There was a striking correlation between the acquisition of immunity in malaria and the cellular changes which occurred in the organs. The disappearance of parasites at all stages of malarial infection could be directly correlated with the activity of the differentiated macrophages of the spleen and liver and to a less extent of the bone marrow. In the initial attack the macrophages were comparatively sluggish and there was a variable destruction of parasites (natural immunity) depending on their virulence, progressive lymphoid hyperplasia ensued, but in the terminal phases of the disease there was great destruction of the lymphocytes. In fatal infections with *P. knowlesi* in monkeys and *P. falciparum* in man no immunity was acquired. In *P. vivax* infections in man and *P. cynomolgi* infections in monkeys the termination of the initial attack (crisis), the subsequent low grade ("developed") infection and the immunity to homologous superinfection were associated with acquired immunity characterized by a greatly enhanced activity of the macrophages and consequent destruction of parasites.

In acquired immunity the macrophages which incidentally originated from lymphocytes were greatly increased both in numbers and activity. This occurred especially in those organs such as the liver, spleen and bone marrow which were strategically placed for the removal of haematogenous material where the blood circulated comparatively slowly. The highly specific nature of acquired immunity pointed to the interaction of specific antibodies in the defence reaction—probably of the nature of opsonins. Attempts to demonstrate these hypothetical antibodies had however proved inconclusive. Talaferro had suggested this was because they were produced in a concentration only sufficient to be operative in certain internal organs such as the spleen. Dr Garnham's paper presented new problems. There were unique facilities in the placental sinuses for contact between the blood elements and macrophage cells out as macrophages were not normally present in the placenta, polyblasts of the lymphocytic-macrophage series must come from outside. The absence of mitosis suggested they did not develop from local deposits of haematogenous lymphocytes and monocytes. Dr Garnham had suggested that expulsion of the placenta removed from the body an appreciable proportion of its cellular defence

with resultant occurrence of parasitaemia and fever which were so common after childbirth. But fatigue and loss of blood also induced attacks in latent malaria and were more probably the precipitant factors.

Dr GREEN ARMYTAGE pointed out that the anatomy of the placenta afforded no real reason why congenital malaria should not be extremely common. Apart from the degenerating syncytial membrane there was trauma which must ultimately break to the continuity of the cotyledon. In this way congenital malaria might occur through infection from the maternal blood in the sinuses. He had seen only one case of congenital malaria in a European baby in Calcutta. In his opinion it was the loss of the placenta with its content of macrophages which was responsible for malarial relapses following delivery and not the effects of fatigue and haemorrhage.

### The Humoral Factor

Colonel J. A. SEXTON pointed out that Dr Garnham's work dealt mainly with the cellular factor in malarial immunity, but there was also the humoral factor. In cerebral malaria Dr Garnham concluded that death did not result from any intrinsic failure of the cellular mechanism but he noted that unphagocytosed parasitized red cells were of great frequency and only a proportion of the reticulo-endothelial cells contained pigment. In the speaker's opinion this suggested that even a hypertrophied reticulo-endothelial system was relatively ineffective in the absence of some specific antibody or specific sensitization of the macrophages. As suggested by Clark in 1915 he considered the expulsion of the placenta by ridding the body of parasites as a factor beneficial to the patient. It was not analogous to the effect of splenectomy in experimental malaria since in the spleen originated the major portion of the protective macrophages of the body. Recently Barber and Clark had reported in highly endemic areas like Macedonia and Panama that the parasite rate in babies up to 2 months of age was comparatively low. This suggested a temporary immunity due to the passage through the placenta of some inhibitory substance from the mother to the child or some substance of an immunizing character acquired during lactation. Another possibility was the passage of hypothetical malaria toxin through the placenta resulting in an active rather than a passive immunity.

### General Discussion

Dr G. W. M. FINDLAY said that though the young fibrocytes of the placenta in Dr Garnham's sections contained trypan-blue this dye was strikingly absent from the placental macrophages. Their cytoplasm stained blue with litmus and readily took up Indian ink and Dr Garnham suggested that failure to take up trypan blue was due to their alkaline reaction. Dr Garnham's results with vital staining were at variance with those of other investigators which indicated that an acid and not an alkaline reaction of the cytoplasm of the macrophages would determine the non-appearance of the dye. The reaction of the somatic macrophages to trypan blue and litmus was very different from that of the placental macrophages as described by Dr Garnham. In his observations were correct it was impossible to deduce from the behaviour of the placental macrophages anything in connection with the behaviour of the somatic macrophages toward trypan blue or to assert that blockade of the somatic macrophages by this dye was impossible.

Dr C. M. WENYON said he found it difficult to believe that in chronic malaria the placenta would take over the work of other organs like the spleen, liver and bone marrow and that these organs would suddenly resume it when the placenta was expelled at the end of pregnancy. The placenta was a sort of angioma with maternal sinuses through which the blood moved slowly. Malarial parasites circulating in small numbers came into these sinuses, stagnated there more or less and began to develop as they might have done in a culture tube. They reproduced by schizogony quite apart

from the ordinary process elsewhere in the body. Lymphocytes and macrophages came in of course and began phagocytosing infected corpuscles. But though malarial infection of the placenta might be induced it did not reflect itself in the number of parasites in the peripheral blood, in this it differed from cerebral malaria. It would appear that what went on in the placenta did not protect the rest of the body against malaria. The immunizing process was going on in the spleen and the removal of the placenta was actually removing a great nidus of parasites and not something which was immunizing against parasites elsewhere in the body.

In reply Dr GARNHAM pointed out that if macrophages were being conveyed from the spleen as Major Mulligan suggested one would expect the peripheral blood to show those cells in greatly increased numbers, but only the lymphocytes were increased in the peripheral blood. Colonel Sinton had suggested that infants did not develop malaria until 2 or 3 months old. In Kenya he found it a fortnight after birth and by 2 months at least 30 per cent of the babies were infected. Splenomegaly in Kenya due to subtertian malaria was a comparative rarity. When found it was nearly always associated with quartan or benign tertian malaria. He agreed with Dr Wenyon's conception of the placenta as an extraneous tumour affording conditions similar to the culture tube: there was certainly a much greater concentration of parasites in the placenta than in the peripheral blood.

### ENGLAND AND WALES

#### Birmingham United Hospital

The Birmingham United Hospital, consisting of the General Hospital founded in 1766 and the Queen's Hospital founded in 1840, has issued its third annual report. The annual income from all sources rose during 1937 and amounted to £161,705, of which £22,721 represented subscriptions and donations. The ordinary expenditure was £168,265, and reckoning in certain extraordinary receipts and expenditures, the working deficiency for the year comes out at £3,803. In explaining a rise of £10,000 in expenditure the compilers of the report point out that additional departments have been inaugurated and developed and research facilities extended. In the General Hospital a new department for radium-beam therapy has been opened, Lord Austin and Lieutenant-Commander Engelbach generously providing one gramme of radium and necessary apparatus, and the National Radium Commission lending a further gramme. Lord Austin has also provided a fourth deep x-ray apparatus. At the Queen's Hospital one outstanding development in 1937 was the establishment of a department of plastic surgery. Birmingham is on the threshold of important hospital developments, and the new hospital at Edgbaston is the subject of a progress report. There will be no unnecessary delay in the assumption by the United Hospital of the responsibilities for the new buildings and service with the largest possible number of beds for which nursing and domestic staffs can be obtained. From then onwards expansion will take place as quickly as possible but it is pointed out that to provide an entirely new and complete organization to full capacity will take some time, especially with a hospital of such modern design and containing all the numerous departments connected with the special needs of a medical school.

#### A Pharmaceutical Jubilee

A luncheon to celebrate the jubilee of Boots Pure Drug Company was held at the Savoy Hotel on June 2. The chairman was Lord Trent, and the company included the

Minister of Health (Dr Walter Elliot), Lord Horder, and several representatives of the medical and pharmaceutical professions. The chairman said that the word "romance" was often misused, but its use was surely justified in describing the progress of the business which was started by his father, Jesse Boot, in Nottingham in 1838. The one small druggists' shop had been multiplied to close upon 1,200, and the one boy assistant had become a staff of 22,000, of whom 7,000 were employed in the factories that supplied the shops. Lord Trent added that the chief pride of his firm was to regard itself as a servant of the community in all matters pertaining to health and cleanliness, and, in its dealings with its workpeople, a modest contributor to that unprecedented social progress which had coincided with its own history. Dr Elliot, replying to the toast of "His Majesty's Ministers," said that the enterprise conceived in the back street of a provincial town had exemplified many of the qualities which had made the English people great. The country was enormously indebted to the pioneers of industry like the late Jesse Boot, first Lord Trent. Goose Gate, Nottingham, had proved the gate of the goose which laid the golden eggs, and, of course, the Government in the person of the Chancellor of the Exchequer welcomed all such prolific fowl. But such firms were also to be congratulated because they gave the example and set the pace for social developments which in due time the Government adopted for the whole community. A real tribute was due to Jesse Boot as a prince of shopkeepers. Dr Elliot went on to speak of the vast extent of the pharmacy business and the skill and care of dispensers. Viscount Wolmer proposed the health of "The Guests," and especially welcomed the presence of the President of the Pharmaceutical Society and the Lord Mayor of Nottingham. A response was made by Mr W. J. Jordan, High Commissioner for New Zealand.

### SCOTLAND

#### Revision of School Health Records

The Department of Health for Scotland has revised the system of school medical inspection and preparation of school health records, and the new scheme is to come into operation in Scotland at the beginning of the next school session. In a circular which the Department has issued to education authorities explaining the new procedure it is pointed out that, while under the existing arrangements much interesting and valuable information has been made available, experience has shown that there are various ways in which improvements can be made. It is not possible under the present system to make full use of the data obtained from school medical examinations because the results are summarized in terms of defects and do not indicate the number of children involved. The new scheme will provide for information being furnished with the object of reviewing from year to year the progress of children with remediable defects. It will also give a clearer picture than has previously been obtainable of the actual physical state of the school population.

#### Recruitment and Conditions of Service of Nurses

The committee which is inquiring into the recruitment and conditions of service of nurses in Scotland has held two further meetings at which evidence was given by representatives of Aberdeen Royal Infirmary, the Victoria Infirmary of Glasgow, the Educational Institute of Scotland, the Medical Women's Federation, the Royal Medical Psychological Association, the General Nursing Council for Scotland, and the Royal College of Physicians of

Edinburgh This completes the oral evidence which the committee is likely to receive and the committee is now engaged on the preparation of its report

### Presentation to Cupar Doctor

Dr John Macdonald, who has practised in Cupar for forty six years, was presented on May 27 with an inscribed silver salver and a cheque for 250 guineas on behalf of patients in the district and colleagues in the profession Dr Macdonald who is a native of Tobs-mory, graduated M.B., C.M. at Edinburgh in 1885, and after spending some time in London and in assistantships settled in Cupar in 1892 where he became one of the best known practitioners and rendered valuable services to the district in the establishment of the Adamson Hospital

## Correspondence

### Planning of Maternity Hospitals

SIR,—I am in complete agreement with your eulogy of Queen Charlotte's Hospital, and I am sorry if anything which I have written has given the impression that I have overlooked the work of Drs Colebrook and Fry and the other members of the splendid research organization at Hammersmith. The application of much of the knowledge which they have given us is now part of the daily routine work of hospital administrators as well as of obstetricians. I do not think there is any serious risk that such an institution will perish of inanition but hospitals such as this are not going to be built in every little town, and I suggest that we should keep the discussion to the question whether additional new accommodation should be provided in connexion with general hospitals or in independent special hospitals. The "ideological" consideration which prompted my original letter was the desire to see established in the country a service which will meet the needs of all women during pregnancy and in childbirth and not merely care for a selection of the normal cases.

Little special maternity hospitals may be very beautiful institutions but like pirate buses, they skim the cream of the traffic and by so doing they increase the difficulties of those who have to provide a service for what is left. It is true that the normal maternity patient is not a sick woman but a proportion of sick women become pregnant and of pregnant women become sick. If they are not to be admitted to maternity hospitals where are they to go? Must they be nursed at home, or will they be sent to a general hospital, where presumably there will not be a staff qualified to care for such cases?

Whether there should be separate domiciliary accommodation for the nursing staff attending maternity cases is a matter on which there is a difference of opinion. If it is of vital importance, what is to be done about the housing of the nurses who attend the morbid cases which occasionally occur in the best maternity hospitals?

To take the points of your criticism in order

(1) I agree that the great bulk of the work of a maternity hospital concerns normal cases. The total maternal mortality is a very small percentage but I am sure you do not suggest that it is not important.

(2) The medical and surgical complications of pregnancy and labour are relatively uncommon, but it is foolish to

ignore them. In Walton Hospital in 1937 there were 2,958 confinements. Among the cases admitted were 222 in which there was some complicating condition apart from the ordinary toxæmia of pregnancy and the complications of labour. This figure included cardiac disease 46, pneumonia 18, pulmonary tuberculosis 16, acute appendicitis 2, terminal ileitis 1, ovarian cyst 3, erysipelas and cellulitis 3, renal calculus 2, chorea 3, mental disturbance of various forms 6. In addition there were 406 abortions. The principal special maternity hospitals may number among their staffs men qualified to treat these cases but will there be such staffs in the countless little hospitals which will be built if the policy which you advocate is carried out?

(3) The emergencies of a maternity hospital are not invariably obscure.

(4) In many maternity hospitals the pathological investigation of the bodies of those who die or are stillborn is very incomplete. In a general hospital this work comes in the routine of the pathological department and a keen obstetrical resident is not tempted to make an examination himself.

(5) There are advantages in treating cases of puerperal sepsis in a ward attached to a medical unit. Hardly any hospitals have a sufficient number of cases of puerperal septic infection to keep a staff of nurses employed exclusively on this work. The variations in the numbers lead to wide fluctuations in the amount of work to be done but if in the same unit there is a medical ward to which selected medical cases are admitted there is sufficient alternative work to keep the nursing staff together. The nurses can be given special training they make no contact with normal maternity cases yet they remain under the direction of the staff of the maternity department. In my experience this arrangement gives the patients the best chance of recovery.

It does not appear to me to be more difficult to build a department of fifty to sixty beds in connexion with a general hospital than as a special hospital. It will certainly be more expensive to build and administer the special hospital. The insignificant size of the maternity units of many of the important general hospitals is due to the fact that the good will energy and money that might have made them larger have been diverted to special maternity hospitals. I hope that this mistake will not be made on a large scale in the developing municipal service.

The point in your annotation to which I wished to draw attention was the statement that the recommendation of the Departmental Committee was not in accordance with the lessons of experience. The issue under discussion is of great practical importance and I hope it will not be decided on inadequate evidence—I am, etc.

Liverpool May 30

HENRY H. MACWILLIAM

### Regional Enteritis

SIR—I read with interest Mr W. H. Ogilvie's exciting forecast of surgical things to come and with attention his comment on regional enteritis (*Journal* June 4 p. 1193). I have had an opportunity of dealing with three of these cases. The first was one of terminal ileitis at the time of operation I was unfamiliar with the condition but judged it to be inflammatory and more likely to settle down than to do anything else. I left it alone. The second displayed that very curious segmental distribution of the enteritis which has been described by several writers. I left this alone too. Interference to have been effective would need to have been very extensive. The third case I encountered a few months ago. It involved the upper jejunum, but in other respects conformed to the first. It was threatening to become obstructive so I did a short-circuiting operation.

All these patients made rapid and uninterrupted recoveries. Only in the last were the symptoms at all menacing, and anastomosis seemed to be all that was required to put them right. Unfortunately it has been impossible to follow up the first two, and the last has been too recently operated on to be considered out of the wood. She is returning to hospital in a few months for a hysterectomy which had been arranged for before she developed the enteritis and there will be an opportunity of examining the bowel. At least it can be said that in none of these cases did the disease "continue to spread," and it can be surmised that resection is not the only line of treatment especially when it involves such an extensive procedure as removal of caecum and ascending colon as well as small intestine.

Unexplained enteric stenosis is not an uncommon finding. I have seen a multiple stenosis of the ileum which might be explained as an end-result of a segmental ileitis and another localized stenosis of the descending colon which might have had a similar explanation. Is it possible that fibrosis is the most probable outcome of this type of inflammation and that it is best facilitated as well as anticipated by anastomosis?—I am, etc

London W 1 June 4

STEPHEN POWER

### Excision of the Patella

SIR—Does Mr A C F Halford (*Journal* May 28, p 1179) desire to put the standard of bone surgery back to the level at which it was sixty years ago? In the days when Lord Lister worked it might have been considered a severe test to open a knee-joint, but, thanks to the results of his work, to open up knee-joints without introducing sepsis is now the everyday lot of a busy orthopaedic surgeon. In the time of Lord Lister fibrous union, malalignment, or late arthritis may have been accepted as the inevitable, or unfortunate, sequel to fracture of the patella. The operation of removal is an attempt to make the function of the knee-joint perfect even after this fracture.

Damaged tissue can be saved by the antiseptic method. What does this mean? A fracture of the patella may be wired with perfect antiseptic technique, yet aseptic necrosis may give rise to fibrous union. Tilting of the fragments may still take place, leading to friction arthritis, introduced infection is not the usual cause of non union. Apparently one must learn to accept the fact that the patella, like the appendix, is superfluous—a recessive structure. Mr Brooke, in his article in the *British Journal of Surgery* (1937, 24, 733), traces this recession in animals. Fast moving animals do not require a patella either as part of a lever system or as a protector to the joint. In man, except for kicks or bangs with a hockey stick the knee does not sustain sufficient direct minor traumata to need a shield for protection. In kneeling which is probably the most simple common trauma, the patella takes no part, it recedes up into the intercondylar notch of the femur. Patients do not miss the bone after its removal. One of my early and very successful cases was that of a roof plumber: his patella was removed for a comminuted fracture. He now climbs up his ladders with full power of extension, and then crawls about on the slates. In the arthritis cases the loss of protection that may result from removal of the patella is small compared with the relief of pain that follows, since there is no friction between the patella and the intercondylar notch of the femur.—I am etc

London W 1 May 29

G O THURPETT

### Treatment of Carbuncles

SIR,—Carbuncles and their first cousins, boils, have afflicted humanity since the beginnings of time. Was not Job cognizant of the agony of boils (Job ii, 7)? They are mentioned in Exodus ix, 9–11, 2 Kings vi, 7, and Isaiah xlviii, 21. They affect indiscriminately men and women, the adolescent and the aged, the poor and the rich, the robust and the debilitated, men largely predominating. Like the common "cold," their treatment has been most unsatisfactory, as witness the "cures," which are vast in numbers.

One procedure in treatment is definitely bad—namely incision. No pus is evacuated, and spaces are opened for infection to spread both locally and systemically. Sir James Paget was the first to deprecate interference. He once had a patient who, according to Sir D Arcy Power, refused operation and surprised Sir James by getting better without, and with less disfiguration than those upon whom an operation had been performed. One of the oldest treatments (still practised in rural areas) was the plentiful application of hot fresh cow dung. This was apparently as efficacious as it was painful. In spite of its disgusting nature this treatment is not without interest. The dung, on caking provided complete physiological rest, a condition so beloved by Hilton the author of that classic *Rest and Pain*. It also exerted a certain degree of suction increasing the barrier action of the solid oedema associated with these conditions.

The treatment I bring forward is a modification of that of Dr J C Lyth, advocated in his thoughtful and instructive article in your columns. Since its publication I have used it on five occasions—two on the back of the neck, one on the arm, one on the eyebrow, and one on the thigh.

It consists of the application of a small pad of gauze soaked in saturated sodium sulphate on the carbuncle and then hermetically sealing the whole area and for some distance beyond, with elastoplast and leaving for three days when it is found that the site is elevated by a collection of blood and pus. The slough is then in most cases lying free in its base, ready for removal with forceps. In four of the cases the surprising feature was the entire absence of pain, in these the skin had disappeared. In the fifth case the pain was described as terrible, but the slough had separated in three days. In this case the skin was not broken. Dressings are continued every three days until healing has occurred. There is little excoriation, which is a common feature in these cases, and the final scar is very satisfactory.

Since Dr Lyth's article (1935) appeared there have been two very interesting papers by Sir David Wilkie (1936) and Dr G Ovens (1937) recommending elastoplast. There is no question but that the treatment by elastoplast, pure and simple, is on sound lines, giving as it does physiological rest and traction. To my mind, however, the objection lies in the fact that pressure is exerted everywhere including the carbuncle where pressure should be avoided. In the method described the gauze takes the pressure off the site of the carbuncle. What is far more important the osmotic pressure of the hypertonic sodium sulphate is enormous compared with that of the elastoplast and this acts in the opposite direction.

The modifications to Dr Lyth's method lie in the fact that the dressing is left on for three days instead of being changed every twelve hours and in the use of elastoplast as a *sine qua non*. The idea of allowing the carbuncle to stew in its own juice, bathed in laudable fix for three days is not new. I was informed that in Buenos Aires which has always been up to date it was customary

as long ago as 1923 to keep compound fractures to 4 or even weeks without changing the dressings in the basement of the hospital. In spite of the stench many cases did remarkably well. There is to-day a definite swing of the pendulum in favour of less frequent dressing.

Another interesting feature of sodium sulphate solutions is their freedom from the development of moulds such as readily grow on the commonly used glycerin and magnesium sulphate. As I understand there are moulds which grow on almost anything including concentrated sulphuric acid it would appear that Dr Lyth has discovered an almost ideal anti-septic. As a matter of interest I have had some sodium sulphate for three years which is only now showing mould formation. Surely further practical uses can be made of this unique property—I am, etc.

### Multiple Benign Sarcoid and Tuberculous Ulceration

SIR—The ultimate diagnosis of the case described under the above heading on March 26 (p. 673) was derived from Dr J. M. H. MacLeod's statement that "microscopical examination showed an architecture which was typical of the multiple benign sarcoid of Boeck" and as Dr MacLeod not only carried out microscopical examination of the lesions but also had clinical charge of the case during part of the patient's stay in hospital the alternative diagnoses suggested by Dr John T. Ingram in his letter in the *Journal* of April 16 (p. 872) were hardly likely to be overlooked. As mere reporter of the case I feel that it would be presumptuous of me to question the specialist opinion of Dr MacLeod and equally presumptuous to wave aside the criticism born of experience, of Dr Ingram.

I regret that I have little information to add to that already published, particularly as I do not have my original notes with me in this country. X-ray examination of the chest was performed but revealed nothing of significance. The Mantoux reaction was not investigated. As reported none of the therapeutic measures employed had any appreciable effect upon the skin condition, although the leg showed some improvement and after some weeks the patient left hospital and was not available for observation in the out-patient department—I am, etc.,

Glasgow June 2

### Nasal Sinusitis in Childhood

SIR—May I be allowed to make one or two comments on the treatment of allergic sinusitis so interestingly discussed by Mr J. Bernstein in the *Journal* of May 28 (p. 1180). First is there such a condition as allergic sinusitis except as a result of secondary infection? There can be no more acute allergy of the nose than occurs during hay fever at its height when the nose is entirely occluded and the orifices of the sinuses blocked but can there be said to be sinusitis? In more chronic conditions where the air-borne protein as house dust is ever present true sinusitis may occur from a secondary infection as happens sooner or later to all patients with allergic asthma, the cedematous urticarial condition of the mucous

mucous membrane favouring this. Group testing with proteins should always be followed by testing for the individual proteins—dust and dog hair etc—otherwise there may be a slaughtering of innocents that is quite unnecessary. The avoidance of house dust is impossible and desensitization should always be carried out and is remarkably effective.

I do not follow why the patient should sleep with the head uncovered nor the necessity for a basal diet avoiding salt, wheat and wheat products, eggs, milk, and pork in any form. Surely the dermal reactions can straighten the sinuses out and avoid such wholesale restrictions as are practically impossible for the hospital class to carry out. While mucopus usually suggests the presence of micro-organisms its absence is not proof that the cause of the paroxysmal rhinitis is not of a microbic nature and discordable with a post-nasal swab. In short I believe the treatment of these cases of paroxysmal rhinitis is even simpler than Mr Bernstein suggests. The proteins to which the patient is sensitive can be discovered and effective desensitization is available. The offending micro-organisms can be isolated and the correct vaccine used. The necessity for calcium, vitamins, and especially ephedrine is then avoided. Where the mucous membrane is excessively tender zinc ionization is extremely effective. Lastly, there will always be a few cases in adult patients that will remain unbenefited by all endeavours. It is in these cases that the removal of spurs and other intranasal deformities at the hands of the rhinologists proves so effective—I am, etc.

London W 1 May 30

FRANK COKE

### Hearing Aids

SIR—I have been impressed with Mr. Cleminson's article on this subject in the *Journal* of May 21 and I feel it desirable that the medical profession should realize what can be done to assist the deaf and should be able to advise their patients regarding a suitable aid. In the past these matters have been dealt with mostly by certain firms who advertise widely and we all know of people who have been persuaded to buy expensive instruments that have proved of little use.

I have suffered from increasing deafness for the past fifteen years. The simple type of electrical aid proved of comparatively little assistance and although I practise a specialty in which hearing is not of primary importance I was becoming embarrassing to my colleagues and a trial to my friends. The development of the valve aid has revolutionized the whole position. At medical meetings, dinners, etc. with fifty to one hundred people present, I am now able to hear nearly every word of the discussion speeches etc.

I would refer particularly to Mr. Cleminson's remarks on the subject of bone conduction. The Medical Research Council's report No. 219 was issued at a time when there was no firm who made a valve aid fitted with this type of receiver. That is not so to-day. For nearly six months I have used one of the aids illustrated in Mr. Cleminson's article. I have become so dependent on it that I have bought a second instrument as a spare because I should feel completely lost without it. I should like to point out that people with middle ear deafness frequently have good bone conduction, a fact which is often not appreciated by firms who make quite excellent air-conduction aids and tend to overlook the usefulness in these cases of bone-conduction aids—I am, etc.

C. H. C. DALTON

**"Cyclopropane Erythema"**

SIR—I was very interested in Dr Victor J Keating's report concerning the above (*Journal*, June 4, p 1235), as I have recently seen an exactly similar case—namely, a rash closely resembling "ether erythema," but rather more rapid in onset and more evanescent, occurring in a female under 30 who had received as premedication omnopon and scopolamine. She was of rather fair colouring, the type which one associates with odd reactions. I have used cyclopropane pretty extensively, but have only once observed the occurrence of any rash—I am, etc,

June 6

H W LOFTUS DALE  
Honorary Anaesthetist, Royal  
Buckinghamshire Hospital

**Sterilization of Syringes**

SIR—I should like to emphasize that if, as referred to by Mr Delisle Gray in the *Journal* of June 4 (p 1237), the syringe and needle are thoroughly cleaned immediately after use then all that need be done is to wash through the syringe and needle with water, spirit, and then ether, after which they can be dismantled and dried by shaking in the air. Before use, assemble and wash through with ether, spirit, and boiled water, and then they are ready for use.

My experience is that some medical men think that once they have put down a syringe somebody will clean it for them, and I have even seen a needle full of blood dropped into spirit. This is not I assume a rare thing for a locum or a partner to find, nor is it uncommon to hear that 'a syringe has become stuck,' in most cases due to the presence of old blood clot—I am, etc,

Fitcham June 6

RICHARD A MANCLARK

**Assistance to Medical Students from Austria**

SIR—As the matter is one which concerns the profession as a whole, I enclose hereunder a letter which has been circulated to the Deans of the Medical Schools in the British Isles. If a medical education from the first year could be assured for a group of students in the manner indicated, lives at present deprived of hope and prospects would again have meaning. Homes would also be needed, but it is not to be doubted that medical men and others in a position to do so would be gladly forthcoming as adopters. I hope and believe that the example of the London Hospital will be followed elsewhere.

We are all very naturally exercised about the treatment and unhappy prospects of our colleagues in Austria. I think there is general agreement in the profession that there is no longer room for any great increase in the number of foreign doctors allowed to practise in this country and that the best we can do where possible is to offer asylum to individuals.

The question of the medical student seems to some of us to be in a rather different category, and I am wondering whether we might not make some concerted effort to provide opportunities for a limited number of Austrian medical students in the British Isles for whom racial origins or political views have made life in their own country no longer possible.

The London Hospital I understand from Dr Clark-Kennedy the Dean has generously undertaken to take one student free of charge for the whole of his medical curriculum on the understanding that his board and lodging can be privately provided.

I would like to offer the suggestion that each medical school should undertake the free education of one student in this way and on these conditions. You will appreciate that this is a very different thing from allowing dilution with Austrian Jewish practitioners who obtain a quick qualification at a university in this country. By the time he is qualified

a student entered from the beginning of his course would be eligible for naturalization. By that time, also, we may anticipate that the high figures of entry into the profession will in all probability have fallen off.

'I shall be most grateful if you could bring this suggestion to the notice of your school council.'

—I am, etc,

Cambridge, May 30

JOHN A RYLE

**The Kettle Memorial Fund**

SIR,—In the issue of your *Journal* dated May 28, 1937, an appeal was made to the friends and admirers of the late Professor E H Kettle, FRS, for subscriptions towards a Memorial Fund. There has been a generous response to this appeal and a total sum of £730 18s 6d has been received. This sum has been invested in 3 per cent Redemption Stock 1986/96, and a trust fund has been established, with the following trustees: Professor J H Dible, Dr W E Gye, FRS, Professor G Hadfield, Professor W D Newcomb, and Colonel A H Proctor.

It was decided by the Committee that the best method of commemorating Professor Kettle would be by an annual lecture to be delivered in rotation at the medical schools with which Professor Kettle had been associated—that is, the British Postgraduate Medical School, St Bartholomew's Hospital Medical School, the Welsh National School of Medicine, and St Mary's Hospital Medical School, and that the choice of lecturers and arrangements for the lecture in any year should be made by the school at which the lecture was to be delivered.

We are informed that the British Postgraduate Medical School have invited Professor W W C Topley, FRS, to deliver the inaugural lecture. He has agreed to do so and the lecture will be delivered in the autumn—I am, etc,

London, W, June 1

A H PROCTOR,  
Secretary of the Memorial  
Committee

**The M.R.C.P. and Psychiatry**

SIR—A point which perhaps did not receive sufficient emphasis in the letter of 'A M O' (*Journal*, May 14, p 1071) is that insistence on possession of the M.R.C.P. as a necessary step to promotion appears to be a policy not general throughout the service of the London County Council, but confined to its mental hospitals department. That it is not demanded by the Hospitals and Medical Services Committee may be inferred from a scrutiny of the list of recent promotions to senior ranks in that service, but why this difference in two departments of one public authority should exist is not easy to understand. On the whole, medical superintendents of mental hospitals enjoy salaries and emoluments on a scale lower than those of London County Council hospitals comparable in size but under the control of the Hospitals and Medical Services Committee, so that, though their responsibilities are presumably considered to be less than those of their confreres in general hospitals, they are none the less expected to attain a higher standard of medical education. Furthermore, in the mental hospitals service not only is the junior medical officer expected to qualify for promotion by passing this stiff examination, but he is also asked to undertake original work, and that he does not do so to the extent which facilities for research in the service offer is to be attributed very largely to the absorption of all his spare time in study and attendance at classes over a long period. In other words, this insistence on possession of the M.R.C.P. by medical officers seeking promotion has nearly succeeded in killing research in the mental hospitals of the London County Council. Is this progress?—I am, etc

May 26

"MEDICAL SUPERINTENDENT"

## Medical Notes in Parliament

The Intoxicants Bill, which has passed the House of Lords, was read a second time in the House of Commons on May 31 and has been referred to a Select Committee. The Prevention and Treatment of Blindness (Scotland) Bill and the Young Persons (Employment) Bill were read a second time in the House of Lords on June 2. The Mental Deficiency Bill is down for further consideration in the House of Commons on June 16.

The Government will introduce and hopes to pass this session a Bill empowering Trade Boards and Agricultural Wages Committees to provide for holidays with pay and enabling the machinery of the Ministry of Labour to be used in the administration of holiday schemes. The Government will consider later the question of general legislation on this subject.

On June 2 Lord Horder moved the second reading of the Funeral Directors (Registration) Bill to set up a register of undertakers or funeral directors with a board of control over those carrying on this business. The Earl of Munster, speaking for the Government said there was no cogent medical reason for the Bill. The Public Health Act 1936 gave powers to local authorities. Lord Horder then withdrew his motion for second reading.

### Detention of Mental Defectives

In the House of Commons on May 30 Dr ELLIOT moved the second reading of the Mental Deficiency Bill. He said that the necessity for the Bill arose from a decision of the Court of Appeal. The case turned on the question of the interpretation of Section II of the Mental Deficiency Act 1913. The Act said that an order should expire at the end of one year unless continued under certain procedure and the Board of Control considered they had a right to regulate their procedure. Before the Board of Control could continue an order they had to investigate the documents concerned and the Board acting on legal advice had proceeded for many years on the view in general that provided the consideration of the special reports and certificates had been concluded by the Board and they had satisfied themselves in due time that the continuation of the order was required, the final sealing and issuing of the order might be done administratively with such reasonable delay as was unavoidable. That view was upheld by a Divisional Court of the High Court but the decision was reversed by the Court of Appeal. The Government had come to the conclusion that the reasonable latitude of one month should be allowed. The Bill also validated orders which had been invalidated by the previous assumption.

### POWERS OF BOARD OF CONTROL

Mr RHYS DAVIES said that the Opposition did not intend to oppose the Bill. At the same time he thought that Subsection (2) of Clause 1 went very much further than giving an extension of one month to the twelve months provided by Section II of the Act of 1913 and there was some apprehension that the subsection would do more than indemnify the Board of Control against errors which had been committed probably in good faith. He asked if the subsection did not increase the power of the Board of Control to detain persons in institutions and enabled the Board to do things which they could not do at present.

Were they right in the assumption looking at the increased figures of mental defectives in this country that the increase was natural or did it result from a closer diagnosis and a certainment of cases? The figures were appalling. The number of mental defectives under care at the end of 1936 was 82,726 and there was an increase of 3,983 under care in 1936 over 1935. Not all these cases would be affected by the Bill but

a considerable number would be so affected. He was rather alarmed to find that the total of imbeciles, idiots and mental defectives apart altogether from lunatics in this country was over 120,000 representing 2.88 per 1,000 of the total population.

Mr MORENO said there was a tendency now with regard to juvenile delinquents to take the view that the erring of the individual was due to mental deficiency and such persons were treated under the Mental Deficiency Act instead of being handed over to the jurisdiction of magistrates. That was having an increasing effect on the number of persons being certified for treatment under the Act.

### THE EXTRA MONTH OPPOSED

Mr LOGAN said that he had seen some of these cases lately and in the majority of them the Board of Control were doing a wonderful work. He was doubtful however whether the Board exercised the supervision essential for the welfare of the individuals placed under their care. He did not think that the Board of Control should have any extension of the period. The individual who was taken into a mental institution could stage by stage have his condition certified and at the end of the twelve months it should be possible to know exactly what his condition was. Twelve months was long enough to detain anybody without certification.

Sir FRANCIS FREMANTLE pointed out to Mr Logan in regard to patients being sent to an institution always for a year that there was a definite provision that the Board of Control might direct the order to expire on the quarter day next after the admission. If the Board were carefully watching as he believed they were over these cases they had the power although they might not always find it advisable to use it to limit detention to three months. Every provision was made by which patients should be detained only after the twelve months when there was a medical certificate by two practitioners including one who at the request of the defective or his parent or guardian or any relative or friend had made a medical examination and considered that it was in the interests of the patient that the order should be made. Therefore it was not a case of wrongful detention under the present law so long as the Board of Control were doing their job. The Bill was an administrative requirement. It was quite natural that the administration might from time to time overstep the mark at the end of the twelve months and in such cases it was advisable to allow the further month. This would not interfere in any way with the patient's release.

Mr EDF said it was very undesirable that anything should be done which might make the period of detention any longer. It would be better for the Board of Control to collect the papers earlier so that the decision might be announced within the period for which the certificate ran.

Sir DONALD SOMERVILLE said the Government had thought it best in the interests of the patient to extend rather than to shorten the time for the medical officers' reports required for the annual review. If the date were put back the medical officer would have to submit the report roughly a month sooner. Under the present scheme the Board would have a certain latitude for the exceptional cases and for the final making of orders. The reports of the medical officers would come in after the Bill was passed on exactly the same dates as at present, so that in normal cases the whole thing could be disposed of before the end of the quarter day. There was no intention of postponing that procedure.

There was no reason why a patient who should be released on his report would not be released as soon after the Bill was passed as he would now. There might be a case where on the original report they would want to refer back for some further report or because of administrative difficulties the order could not be got out before the quarter day. In such a case it was important to have the extra month. If there were a case in which the Board of Control thought that further inquiries should be made the Bill gave time to consider all possible questions that might arise. It was better to give the extra month which the Board had no intention of using for delay to enable the Board to deal with exceptional cases and give them time for the necessary administrative procedure.

Replying to Mr Logan Sir Donald Somervell added that the Board had full power to discharge at any intermediate date. Clause 25 (2) of the Bill said: Any commissioner shall have power to discharge at any time any person detained in a certified institution or a certified house or under guardianship under this Act. There was the further safeguard, in addition to the annual and quinquennial reviews, that every case was reviewed by the visiting justices at the age of 21. Where there was a possibility of recovery and the medical officer or visitor under the local authority so advised there was no reason to believe that that position could not be considered and acted on as promptly after this Bill as before.

Replying to Sir Robert Tasker Sir Donald Somervell said that at every step the Board of Control acted on medical advice.

The Bill was read a second time.

### Nursing Homes in Scotland

The Standing Committee on Scottish Bills sitting at the House of Commons on May 31 considered the Nursing Homes Registration (Scotland) Bill. On Clause 5 (Inspection of nursing homes) Sir DOUGLAS THOMSON moved to leave out the words "who is not a registered medical practitioner" from the subsection which as originally introduced provided that nothing in this Act shall be deemed to authorize any such officer who is not a registered medical practitioner to inspect any medical record relating to any patient in a nursing home. He said that under the Bill as it stood it would be possible for any local authority inspector or Department of Health officer who was a medical practitioner to inspect the confidential records of any patient in a nursing home. That was not desirable. Patients should be able to go into a home with the feeling that their case records were confidential. The provision in the English Act was the same as in the clause as he proposed to amend it. The committee agreed to the amendment and after further discussion of the inspection of nursing homes for other purposes the clause as amended was approved.

On Clause 6 (Power to exempt certain institutions) Mr PETHICK LAWRENCE asked what was intended to be covered by the provision. Sir DOUGLAS THOMSON said it was anticipated that the type of institution which would be exempted would be the large hospitals that were not carried on for profit but were not constituted by special Act of Parliament or by special charter. A local authority was not obliged to leave any of these out and was entitled to refuse an exemption or to grant conditions to the exemption. The clause was approved.

Sir DOUGLAS THOMSON brought forward a new clause (Power to exempt Christian Science homes). He said it was exactly in the same form as a clause in the Nursing Homes Registration Act of 1927 and was now incorporated in the Public Health Act 1936. Christian Scientists were obliged to have a doctor in to attend their children when they were ill and also to notify the authorities of infectious and contagious diseases. Exemption could be withdrawn when the Department of Health was not satisfied that the home was properly carried on and supervised. After discussion the clause was withdrawn. The Bill as amended was then ordered to be reported to the House.

### Medical Examination of Mental Defectives

On May 11 Mr T. HENDERS asked the Secretary of State for Scotland if he was aware that the Scottish Board of Control refused the right of the parents of a person certified by the Board as a mental deficient and an inmate of an institution under the authority of the Board to have an independent medical examination of such certified person and if he would instruct the Board to grant an independent examination on application being made.

Colonel COLVILLE replied that defectives were not certified by the General Board of Control but the Board had a statutory duty to review at stated intervals the cases of all certified defectives. On such occasions the Board might obtain a report by one or more independent medical men.

They were bound to order the discharge of a patient at any time if they were of opinion that he was not, or no longer was, a mental defective. A parent or guardian might apply in writing to the Board for the discharge of any defective on the ground that his mental condition did not justify further detention, and the Board might if they thought fit require the applicant to produce a medical certificate in support of the application. He was not aware of any case in which the Board had refused to comply with the statutory provisions.

### Outbreaks of Anthrax in Angus

On May 31 Mr RAMSBOTHAM replying to Mr Westwood said that during 1937 twenty-two outbreaks of anthrax in Angus, in which twenty-nine animals were affected, were reported by the county authority. In the first quarter of 1938 twelve outbreaks, affecting thirteen animals were reported. Eight of the 1937 outbreaks, and three in the March quarter of 1938 were probably due to the farms having been infected on previous occasions. The source of infection in the other cases was not definitely traced, but it might possibly have been associated with the use on these farms of artificial feeding stuffs which in fourteen cases were known to have been imported from abroad.

### Hospitals in Time of Air Attack

Sir SAMUEL HOARE in the House of Commons on June 1, moved a Vote for the expenses of air raid precaution services. He said that about 400,000 men and women had volunteered their services. So far as training and first aid and anti-gas training were concerned, 11,000 doctors, 13,000 dentists and 22,000 nurses had passed air raid precaution courses. The Ministry of Health had undertaken a survey of the hospital accommodation of the country with a view to air raid precautions. That survey was not complete, but had tended to show that the old distinction between casualty hospitals and base hospitals could not in the conditions of air warfare be fully maintained. It showed that in the organization of the hospital system for air raid precautions the Ministry of Health should be the responsible department. It had been suggested that casualties, instead of being dealt with, say, in the London area, ought to be taken as quickly as possible outside the area of the London attacks, which might be so formidable that it would be difficult for the staff and the doctors of the hospitals to carry on their work. It was also suggested that casualty hospitals ought to be formed on the periphery of London on the lines of the tented hospitals in Etaples during the war, and that as soon as casualties could be moved they ought to be taken to a greater distance. The Government had already tentatively suggested to the Universities of Oxford and Cambridge that they might place the Colleges of the Universities at its disposal.

That was one of several proposals upon which they now wished to come to a quicker conclusion and to have the opinion of experts in the hospitals outside Whitehall. Accordingly he had asked a number of hospital experts to look at this proposal and several other proposals of the same kind and to indicate which they thought most practicable. Those whose opinions he had asked were Sir Charles Wilson, Dean of St Mary's, Mr Girling Ball of St Bartholomew's, General MacArthur, Director General of Medical Services at the War Office, Sir Frederick Menzies of the L.C.C. and the principal medical experts at the Home Office and the Ministry of Health. As to the protection of hospital personnel against air raids and the precautions to be taken by the boards of management of hospitals, the Home Office would issue directions in the next few days which should be extremely useful to committees and boards of management throughout the country.

Mr NOEL BAKER moved the reduction of the Vote. He criticized the proposals of the Government as inadequate.

### CONTROL OF HOSPITAL SERVICES

Dr HADEN GUEST said the first aid posts must be very close together because unless people who had mustard gas

on their clothing reached the post in fifteen minutes or if the liquid were on their hands in five minutes they would suffer as mustard gas casualties. To neglect the mustard gas problem would be foolish. He thought the hospital committee was strong and useful but it should have been appointed long ago. There was not only the question of providing hospital accommodation but the question of how that accommodation was to be controlled. How were the control and organization of the hospital system in London to be shared between the London County Council and the voluntary hospitals, and in what way was the hospital organization outside the London area to be controlled? There was something to be said for making the control of the hospital services of the country into a national service. The committee appointed by the Home Secretary must consider how the hospital service required for air raid precautions was to be co-ordinated with the hospital services required for civilian and for the Army, Navy and Air Force. During the war the whole of this country was covered with a network of hospitals to which men were distributed when brought back from the front in France. What extra provision would be required under the conditions of a modern war? Judging by what had occurred in Barcelona one bomb dropped in a big centre of population in this country might cause casualties equivalent to those caused in a first-class action in the war. Was there any question of increasing the number of hospitals?

Mr GEOFFREY LLOYD replying to the debate said that by the regulations casualty hospitals would be the responsibility of local authorities, while base hospitals were a central Government responsibility.

Colonel NATHAN asked it that applied to voluntary hospitals and municipal hospitals and Mr LLOYD said that it applied to all hospitals. On the question of the possible evacuation of the population from London Mr LLOYD said that it had been worked out with the railway companies that 2,500,000 could be moved fifty miles or more out of London by rail in seventy-two hours.

The Vote for air raid precaution services was then carried by 174 to 95.

*General Medical Service for the Nation*—On June 2 Dr ELLIOT told Mr Gallacher that consideration was being given to the proposals of the British Medical Association in connexion with national health insurance including increases in medical and surgical benefits. He was not yet in a position to indicate the attitude of the Government.

## Obituary

We regret to announce the death of Dr ROBERT STEWART MOWAT which took place suddenly in Edinburgh on May 24. Graduating M.B. Ch.B. in 1894 he obtained the DPH of St Andrews in 1901 and the M.D. in 1909. He was appointed assistant to the lecturer in medical jurisprudence at University College Dundee and subsequently resident medical assistant at Dundee Royal Infirmary. He then returned to Edinburgh and for forty years carried on a large and successful practice. Dr Mowat had been a member of the British Medical Association since 1895. A modest genial kindly man of great personal charm, and gifted with a keen sense of humour he was very conscientious and enthusiastic about his work and ever willing to give sound advice and assistance to a young man commencing practice. Dr Mowat was familiar with all that is best in our literature. He loved our countryside and there without ostentation he revealed his expert knowledge of botany and natural history. A large number of patients, friends and colleagues paid affectionate tribute to his memory at the funeral service on May 27. He leaves a widow and one daughter to whom much sympathy will be extended.

The death took place at his residence in St. Andrews Drive Glasgow on May 28 after several weeks of illness of Dr GEORGE GRAY BUCHANAN, medical officer of health for the county of Renfrew. Dr Buchanan was born at Kilmarnock in 1881 and after graduating M.B. Ch.B. at Edinburgh in 1902 and taking the degree of B.Sc. in public health in 1904 he became assistant to the professor of public health in Edinburgh University. Later he was appointed assistant to the medical officer of health for Midlothian and shortly before the war became medical officer of health for East Lothian. After serving in France and India with the R.A.M.C. during the war he returned to his post in East Lothian and in 1919 was appointed to the position of county medical officer for Renfrewshire. Dr Buchanan was a popular and efficient administrator and took special interest in current methods of disinfection. He is survived by his wife, a daughter and two sons of whom one is a medical practitioner in Glasgow.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

On June 1 Professor H. R. Dean, M.D., Master of Trinity Hall, was re-elected to the office of Vice-Chancellor for the academic year 1938-9.

At a congregation held on May 28 the following medical degrees were conferred:

M.D.—A. W. Williams, R. M. Bolam, J. H. C. Gray,  
M.B. B.Chir.—M. C. Hourstield, D. C. Laverder, G. R. C.  
Peachard, R. D. Holloway,  
M.B.—G. D. Wedd.

\* B. P. Fox

### UNIVERSITY OF LONDON

The Senate on May 18 awarded the degree of Ph.D. in Bacteriology (non-clinical) to F. Himmelweit (St. Mary's Hospital Medical School) and the degree of Ph.D. in Psychology to G. W. Goodall (London School of Hygiene and Tropical Medicine).

### UNIVERSITY OF MANCHESTER

Dr A. D. Macdonald Leach, Professor in Materia Medica, Therapeutics and Pharmacology in the University, has been appointed Dean of the Medical School from July 31 in succession to Professor H. B. Matland.

Dr R. W. Fairbrother has resigned the post of lecturer in bacteriology.

Dr Raymond Whitehead, lecturer in pathology, has been elected to a Rockefeller Fellowship and has been granted leave of absence or the session 1938-9 while working at the School of Medicine and Dentistry of the University of Rochester, New York.

### UNIVERSITY OF ABERDEEN

Professor C. Heymans of the University of Ghent will deliver two lectures in the physiology lecture room, Mansel College, Aberdeen University, on Monday and Tuesday, June 13 and 14 at 5 p.m. On June 13 he will speak on 'Some Aspects of Blood Pressure Regulation and Experimental Arterial Hypertension' and on June 14 he will discuss 'The Role of the Aortic and Carotid Sinus Pressors and Chemoreceptors in the Reflex Control of Respiration'. Professor E. W. H. Cruickshank will be in the chair. The lectures are open to students of the University and others interested in the subject.

### UNIVERSITY OF EDINBURGH

Professor B. P. Babkin, M.D., of the department of physiology, McGill University, Montreal, will deliver two lectures in the anatomy lecture theatre, University New Building, Teviot Place, Edinburgh, on Tuesday and Wednesday, June 21 and 22 at 5 p.m. In the first lecture Professor Babkin will deal with 'The Regulation of the Secretory Activity of the Gastric Glands' and in the second he will discuss 'Conditioned Reflexes'. Their significance in the light of recent work. Students and graduates are invited to attend the lectures.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 28, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 126 (123 in 1937) great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

\* Cases in the last year.  
† In Oct. of 1937 puerperal fever was made notifiable in the  
administrative counties of London

‡ Deaths from puerperal fever in London in primary form in figures for England and Wales (administrative counties) and Northern Ireland

## EPIDEMIOLOGICAL NOTES \*

## Enteric Fever

During the week under review there were 17 notifications of enteric fever in England and Wales compared with 15 in the previous week. 2 were in London—1 each in Fulham and Wandsworth. In Scotland 12 cases of typhoid fever were notified—9 in Roxburgh County belonging to the Hawick outbreak and 1 each in Dundee, Edinburgh and Glasgow where there was 1 death during the week. The source of the Hawick outbreak has now been traced: an employee of the local co-operative store has been found to be a carrier and has been isolated since May 17. It was shown that he handled foodstuffs which had been taken by practically every person who contracted typhoid in the outbreak. Although the water supplies were found to be above suspicion it was decided to continue chlorination in the meantime.

## Diphtheria and Scarlet Fever

In England and Wales notifications of diphtheria during the week dropped from 1110 to 1002 while in London they fell from 164 to 128. Small decreases were noted in Eire and Northern Ireland but an increase was reported for Scotland. Deaths in the 126 Great Towns of England and Wales rose from 26 to 29 and in London from 1 to 3. Of the 29 deaths recorded in England and Wales 2 each occurred in Darlington, Keighley and Liverpool. Of the 6 deaths recorded in Scotland there were 5 in Glasgow and 1 in Edinburgh. There was a slight rise in the notifications of scarlet fever in England and Wales in excess of the median value for the last nine years but in London they were considerably less. Notifications in Scotland dropped from 485 to 362 while in Northern Ireland they rose from 91 to 114 and in Eire they remained at 112 for both weeks.

## Primary and Influenzal Pneumonia

There was a definite fall in the notifications of primary and influenzal pneumonia in England and Wales and in London. The figures both for England and Wales and London remained in excess of the median values for the last nine years. Fewer deaths from influenza were reported in England and Wales, London, and Scotland. In the West Riding (Yorks) 140 (171) cases were notified of which 44 (64) were in Sheffield and 24 (27) in Leeds. In Warwickshire there were 61 (78) cases of which 36 (51) were in Birmingham. Of the 186 (210) cases reported in Lancashire 49 (49) were in Liverpool and 42 (62) in Manchester. Of the 39 deaths from influenza in the 126 Great Towns of England and Wales 5 (2) were in Kingston upon Hull and 2 each in Manchester (2), Stockport (1), Birmingham (4). In Scotland 246 cases of primary pneumonia were notified compared with 252 in the previous week; there were 9 cases of influenzal pneumonia (1 more than in the previous week) and 5 deaths of which 2 occurred in Dundee and 1 each in Edinburgh, Hamilton, and Falkirk. There were 11 deaths from pneumonia in Eire of which 9 were in Dublin and 2 in Limerick. There were 13 deaths from pneumonia (the same as last week) in the ten principal towns of Northern Ireland: 11 in Belfast, and 1 each in Londonderry and Portadown.

## Measles and Whooping-cough

In the 126 Great Towns there were 16 deaths from measles compared with 26 in the previous week. Of these, 6 (10) occurred in London, and 1 each in Kingston upon Hull (2), Leeds, Newcastle-upon-Tyne (2), Doncaster, Bolton, Southampton, West Ham, Preston, Sheffield, Coventry. During the week 949 cases were reported from the LCC elementary schools compared with 942 in the previous week. The average daily admissions to the

Except where otherwise mentioned figures in parentheses refer to the week preceding the one under review.

LCC fever hospitals were 46 compared with 30 in the previous week and the number of cases of measles under treatment in these hospitals on Friday May 27 was 1282 compared with 1364 on May 20. On the same day there were under treatment in the LCC fever hospitals 1009 (1070) cases of diphtheria, 841 (843) of scarlet fever and 22 (23) of whooping-cough. Notifications for the week ended May 28 in the eleven metropolitan boroughs in which measles is notifiable were 460 (348) distributed as follows: Battersea 4 (25), Bermondsey 20 (19), Finsbury 19 (19), Fulham 25 (25), Greenwich 104 (95), Hampstead 18 (13), Lambeth 45 (52), St. Pancras 74 (41), Shoreditch 20 (13), Southwark 23 (13), Stepney 21 (28). In Scotland 380 cases of measles were notified compared with 382 in the previous week; the figures for Glasgow were 123 (129), Dundee 6 (63), Lanark County 45 (38), Aberdeen 44 (41), Falkirk 38 (36), Kirkcaldy 37 (34), Edinburgh 124 (124). During the week there were 11 (10) deaths from measles in the 16 principal towns of Scotland; of these 5 (3) occurred in Dundee, 4 (5) in Glasgow, 2 (2) in Aberdeen. In Northern Ireland there was 1 death from measles in Londonderry County Borough and in Eire the case is in Dublin.

In England and Wales there were 11 (17) deaths from whooping-cough during the week under review of which 3 (11) occurred in London. In Scotland 80 cases of whooping-cough were notified compared with 59 in the previous week while the deaths remained at 2—1 each in Greenock and Motherwell and Wishaw. In Northern Ireland 16 (17) cases of whooping-cough were notified with 2 (2) deaths 3 of which were in Belfast.

## Cholera

During the week ended May 28 18 cases of cholera were notified in Shanghai. In the same week in Burma there were 6 cases with 4 deaths and in Indo-China there were 32 cases. During the previous week—that is week ended May 21—there were 125 cases with 47 deaths reported in Calcutta, 2 cases with 1 death in Bassein, 1 case with 1 death in Rangoon, 10 cases with 17 deaths in Delhi, 7 cases with 2 deaths in Cawnpore, and 1 case with 1 death in Allahabad.

## Plague

During the week ended May 28 there were in British India 3 cases of plague with 3 deaths (in Bassein), in Burma there were 5 cases with 3 deaths. On May 26 1 case of plague was reported in Egypt (in the province of Asyut). During the week ended May 21 18 cases of plague were reported in the Union of South Africa.

## Small pox

During the week ended May 28 5 cases of small pox were reported in Shanghai. During the same week 12 cases were notified in Burma, 2 in British India (1 each in Bassein and Rangoon). In the previous week 27 cases with 22 deaths were reported in Bombay, 27 cases with 12 deaths in Madras and 76 cases with 66 deaths in Calcutta.

## Typhus

During the week ended May 28 3 cases with 2 deaths were reported in Alexandria and 3 cases in Palestine (1 in Jaffa and 2 in the rural districts). In the previous week in Morocco there were reported 175 cases of typhus with 12 deaths mainly distributed as follows: Casablanca 48 cases, 3 deaths, Marrakesh 37 cases, 1 death, Oued Zem 32 cases, 6 deaths, Casablanca 18 cases, Agadir 10 cases, 7 each in Doukkala and Rabat. During the same week—that is week ended May 21—there were 8 cases with 1 death in Alexandria. In Shanghai there were 64 cases with 8 deaths in Palestine there were 8 cases. During the week ended May 7 100 cases of typhus with 3 deaths were reported in Poland mainly distributed by departments as follows: Stanislawow 15 cases, Nowogrodek 13 cases, 12 each in Lublin and Wolynia, 10 each in Lwow and Wilno, 5 each in Bialystok, Kielce and Tarnopol.

## Medical News

Dr T H Sanderson Wells has endowed an annual lecture ship at the Middlesex Hospital Medical School, expressing a wish that the subject to be dealt with should cover the field of the relations between rheumatism and dietetics. The inaugural lecture on Monday June 20 at 4 p.m., at the Middlesex Hospital, will be given by Dr Sanderson Wells, and the second lecture, in 1939, by Major-General Sir Robert McCarrison.

The Imperial Tuberculosis Bureau, in co-operation with the East India Association and the Over-Seas League, is sending out invitations to a lecture 'Tuberculosis: A Key Problem of India,' to be given by Major-General Sir John Megaw, Chief Medical Adviser to the Secretary of State for India, on Tuesday, June 21 at 4.30 p.m., at St Andrew's Hall, Over-Seas House St James's SW. The chair will be taken by the Marchioness of Linlithgow.

The German Society for Psychology will hold its sixteenth congress at Bayreuth from July 1 to 4, when the chief subject for discussion will be Character and Education. Further information can be obtained from Dr O Engelmayer, Hochschule für Lehrerbildung Bayreuth.

The eighth conference of the International Committee of Military Medicine will be held in Luxembourg from July 1 to 4. A simultaneous meeting on international law, organized by the International Law Association, will discuss legislative questions relating to aerial protection, and another will discuss the scientific study of aerial defence against war gases. Invitations to take part in the conference are given to all naval military, and air medical officers whether serving or retired at home or abroad in view of the wide range of the programme technicians are also invited. The fee for membership is 25 Belgian francs for all who are not official delegates of their Government. Reductions in travelling expenses are obtainable. Further information may be had from Colonel Voncken, Office International de Documentation de Médecine Militaire, Liège.

The next meeting of the German Ophthalmological Society will be held in Heidelberg from July 4 to 6 and the ninety-fifth congress of German naturalists and doctors in Stuttgart from September 18 to 21.

The third Congress of the Austrian Society for Roentgenology which was to have been held from September 23 to 25 and the Congress of the Austrian Urological Society arranged for June will not take place. The sixty-second international postgraduate course on the progress of medicine with special reference to treatment will be held in Vienna from September 26 to October 8.

The Croydon Town Council has decided not to allow fairs to be held in future on Bank Holidays at the Shirley Hills, which form part of the gathering ground for the Addington Well—the well from which infection in the recent outbreak of typhoid fever is believed to have spread. The council has also accepted the recommendation of its Typhoid Committee that a special advisory committee of six members of the Public Health Committee and four doctors should be appointed.

After a long discussion Salford City Council on June 1 approved a recommendation of its Finance Committee authorizing the Health Committee to spend an additional £3,825 during the current financial year to cover the cost of the introduction as from July 1 of a 48-hour working week for nursing staffs under the control of the Health Committee.

The notification of undulant fever and psittacosis has recently been made compulsory in Argentina.

Dr Karl Koller of New York, a native of Vienna who introduced cocaine as an anæsthetic into operative ophthalmology, celebrated his eightieth birthday on December 3, 1937.

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors, over seas, should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are:  
EDITOR OF THE BRITISH MEDICAL JOURNAL, Autology, Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7 Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh) and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.) 18 Kildare Street, Dublin (telegrams: *Bacillus, Dublin*, telephone 62550 Dublin).

## QUERIES AND ANSWERS

### Sterilization of Syringes

Dr N PINES (London E 1) writes: It seems to me from recent correspondence in the *Journal* that some members of the medical profession in this country and abroad are still vexed by this problem. I solved it many years ago to my complete satisfaction by adding some thymol to the methylated spirit in any proportion from 1 in 1,000 to 1 in 100. Thymol is readily soluble in alcohol, does not corrode the metal and is one of the most powerful disinfectants in existence. It is strongly irritant to the tissues, and therefore the syringe must be washed out with freshly boiled water before use.

## LETTERS, NOTES, ETC.

### Baby Week

The National Baby Week Council since its foundation in 1917, has worked to improve the maternity and child welfare services and to educate the public in the means of maintaining health during pregnancy and bringing up healthy children. Its efforts have of course received great impetus from the national movement for physical fitness. It is endeavouring to organize "Keep Fit" classes at all infant welfare centres, the object being to give expectant mothers instruction in suitable physical exercises in company with other women. It should be quite easy for classes similar to those arranged by the Women's League for Health and Beauty, the Margaret Morris Movement and the physical education classes organized by education committees to be conducted at maternity and child welfare centres. Weekly exercise would not be sufficient but the mothers would soon be enthusiastic enough to carry out at home the exercises they had learnt at the centre. Systematic exercises can also benefit the young child and the Council also advocates provision of playgrounds for toddlers. It suggests that women's institutes should offer their places, of meeting for "Keep Fit" classes, and that where a suitable hall is not available at the centre local co-operation can arrange for one elsewhere to be used. The Central Council for Recreative Physical Training is willing to provide qualified leaders as instructresses.

In the *Journal* of May 21 (p. 1120) we announced the constitution of the International Academy for Medical Postgraduate Work. The address of the Permanent Bureau is Robert Koch Platz 7 Berlin NW 7.

## EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

## 486 Basal Metabolism in Hyperpnoea

M. GEORGOPOULOS and N. TSAMBOULAS (*Disch. med. Wschr.* March 25 1938 p. 432) report from Athens their observations on the association of a high basal metabolism with a high blood pressure. They note that wide differences of opinion have been expressed on this alleged association since 1923 when Mannaberg published his account of it. The authors believe that the differences of opinion are partly at any rate due to lack of uniformity of technique and to the neglect of certain precautions in the measurement of the basal metabolism. They themselves take the precaution of measuring it only after prolonged rest in bed. They have found the basal metabolism normal in a long series of males suffering from various forms of hyperpnoea and the only male case in which the basal metabolism was raised was complicated by insufficiency of the aorta with continuous slight dyspnoea and nervousness. Less negative were the findings among women who had raised blood pressures and who were classified in three groups: (1) In twelve of fifteen cases occurring at the climacteric the basal metabolism was above normal up to as high as +45 per cent. (2) In all the sixteen cases of hyperpnoea in younger women whose ovaries had been removed by operation or who had been radiologically sterilized, the basal metabolism was much above normal, and considerably more so than in the first group. (3) In none of the fourteen cases seen in older women whose climacteric dated several years back was the basal metabolism above normal. The high basal metabolism in the first group could not be explained away merely as the result of nervousness for when measurements were taken during sleep under the influence of narcotics the basal metabolism was still above normal though lower than before. The same observation was made with the second group.

## 487 Intrapleural Gold Therapy in Phthisis

R. AMAT (*Arch. med. chir. Appar. resp.* 12 4 326) claims good results in the treatment of cases of phthisis in which collapse therapy has failed by the injection of gold compounds intrapleurally. The number of patients treated was thirty-eight. There were twenty-six successes with rapid recovery in fourteen and twelve failures. The treatment is most successful in early cases. Of the thirty-eight cases twenty-nine had a history of from three to six months illness and of these twenty-nine twelve recovered rapidly, twelve were improved and only five failed to benefit. Of the five failures four showed clinical cure after treatment by intrapleural injections of extracts of tubercle bacilli. In twenty-three cases gold chloride was used and in the rest either gold compounds alone or in conjunction with the chloride. The initial dose of the chloride was 0.01 to 0.05 gramme every five to ten days the dose being gradually increased in the absence of excessive reactions. The injections were followed by local and perifocal reactions and there might or might not be general reactions with pyrexia. The presence or absence of a general reaction did not seem to influence the result. In some cases the injections seemed to cause a lengthening or even a complete separation of adhesions either through an effusion raising the intrapleural pressure or because of some modification of the adherent tissues. The total dose of gold may be large. In one case 2.25 grammes of the chloride was administered in fifty injections during six months. The method is not advised in chronic cases where there are large cavities or dense fibrosis. In these cases it may cause pleuro-pulmonary perforation and purulent pleural effusions.

## Surgery

## 488 Sarcoma of the Prostate

L. D. DONAHUE (*Urol. cutan. Rev.* March 1938, p. 176) who records an illustrative case and has collected 144 others from the literature states that sarcoma of the prostate is primarily a condition found in youth. About a quarter of cases have occurred in men in the seventh and eighth decades. The youngest case reported was in a child aged 4 months and the oldest Donahue's case in a man aged 80. The onset is insidious and does not differ from that of other forms of prostatic hypertrophy. The radiation of pain is usually the same as in carcinoma of the prostate—namely through the pelvis and down the extremities. The tumour may interfere with defaecation and cause discomfort in the rectal region. Fifteen out of twenty patients subjected to operation showed recurrence in two or three months. The round-celled type or tumour is the most malignant and the spindle-celled type less so. In Donahue's case bladder symptoms had been present for about a year before operation was necessary for complete retention when transurethral resection was performed. Microscopical examination of the growth showed long spindle-shaped and hyperchromatic cells. Relief of symptoms was obtained but the issue of the case is not recorded.

## 489 Orthopaedic Principles

E. SEREGHY (*Zbl. Chir.* March 19 1938 p. 639) gives an outline of his principles in the treatment of fractures of the long bones. In his experience long-continued extension with small weights will not bring about correction of the displacement. This form of treatment is only used when it is desired to maintain a corrected position and even then the method may often fail. In suitable cases skin traction is used but the author's preference is for skeletal traction whenever displacement is marked. Open operation is only very rarely resorted to in recent fractures and plates or screws are never used for fixation. A thin bronze aluminium or steel wire (0.5 to 0.8 mm in diameter) is recommended. Compound fractures are treated by gradually increased skeletal traction reaching 8 to 10 kg on the tenth day. After two weeks reduction may be attempted if necessary and if indicated by a healthy state of the wound. Fractures with little displacement and fractures in which displacement has been corrected are fixed on plaster splints or in bivalve plaster-casts. The affected limb is kept elevated until the traumatic swelling has disappeared. After eight to ten days or such treatment patients with fractures of the leg may then be put into a walking plaster which is padded with zinc gelatin applied directly to the skin. Longitudinal bandages can be incorporated with the zinc gelatin to allow or traction being exerted during the application of the plaster.

## Therapeutics

## 492 Cod Liver Oil for Tuberculous Pharyngitis

According to A. L. BAXBY (*Arch. Otolaryng.* Chicago February 1938 p. 154) the curative action of cod liver oil is due to the presence of large amounts of vitamins A and D. Further, American cod liver oil contains more iodine than most ordinary foods. 10 ccm of high grade medicinal oil would supply the daily iodine requirement which is 20 to 100 microgrammes. A less well-known use of cod liver oil is as a local application in tuberculous pharyngitis and laryngitis. The author has made a careful

clinical study of the healing properties of cod-liver oil when used as a spray or as a dressing. A patient with lupus vulgaris was first selected for treatment. The disease was of six years' duration, and involved the face and the entire extent of the skin of the left arm. Small pieces of gauze soaked in cod-liver oil were applied to the involved areas twice a day. Complete healing resulted in eight months. Tuberculous lesions of the throat and larynx were treated by spraying the ulcerated areas with cod-liver oil three times a day. There were only a few patients who did not tolerate cod-liver oil because of its fishy taste. Pharyngeal and laryngeal ulcers showed rapid epithelialization and healing. Laryngeal tuberculosis with oedema was resistant to this treatment. The analysis of ninety-one patients who were treated for from two to eighteen months gave the following results: 26.3 per cent remained unimproved, eight of these patients dying during the course of the treatment; 46.2 per cent improved subjectively and objectively; 27.5 per cent were healed. In the majority of the last group the healing of the tuberculous lesions was established before the patient had recovered from the pulmonary tuberculosis. It is reasonable to assume that the healing was accomplished or accentuated by the local application of cod-liver oil.

#### 491 Hyperthyroidism

H. BERNHARDT (*Med. Klinik*, March 4, 1938, p. 285) discusses the medicinal treatment of hyperthyroidism. He believes that the number of patients suffering from hyperthyroidism has been on the increase during the last forty years. He recommends Plummer's pre-operative treatment. In cases in which iodine is badly tolerated he advises luminal, glucose, etc. In cases of coma, which is usually accompanied by nausea, vomiting, and diarrhoea, he gives iodine parenterally, in very severe cases he injects intravenously 2 c.c.m. of "endojodin" (corresponding to 0.22 gramme of iodine) diluted with 20 to 40 c.c.m. of a 30 per cent solution of glucose. The injection can safely be repeated two or three times during the day. In some cases calcium iodide seems to be better tolerated than potassium iodide. In a number of cases ammonium fluoride has been used successfully instead of iodine preparations. Good results have been obtained from ergotamine in the form of gynergen. The results of medicinal treatment are greatly enhanced by a lacto-vegetarian diet. Iodine therapy may be advantageously combined with the administration of arsenic.

## Radiology

#### 492 Encephalography of Subdural Haematomata

T. J. C. VON STORCH and D. MUNRO (*New Engl. J. Med.*, January 6, 1938, p. 6) have carried out three ventriculographies and thirty-two encephalographies in a series of thirty-five cases of subdural haematoma. All the exposures were made with the patient sitting erect throughout the procedure. The examinations proved that the value of encephalography in the diagnosis of fluid haematomata was negligible; it may however reveal large clots of long standing. Until further information is available it is unwise to lay too much stress upon the presence of unencysted air as an indication of the presence of subdural haematoma. On the other hand it has been proved that encephalography is a valuable adjunct in the diagnosis of thin solid subdural haematomata. Gross compression of one lateral ventricle with a shift of the whole ventricular system to the opposite side and homolateral obliteration of the sulcal shadows is suggestive of a large flat intra-cranial mass. Such a picture is found infrequently and then only in cases of large well-organized subdural haematoma. In the case of mixed and fluid varieties of haematoma the encephalographic picture is less frequently it shows little or nothing abnormal.

Certain signs, however, are of diagnostic importance. In order of their importance they are: (1) A slight but definite depression of the roof of one lateral ventricle with or without a shift of the ventricular system (and often of the falx) to the side opposite to the depressed ventricle; a slightly enlarged contralateral ventricle, variable contralateral hemispheric changes, and some decrease of the homolateral hemispheric markings. (2) Small multiple or large cystic areas of subdural hemispheric air associated with normal or moderately enlarged ventricles and variable subarachnoid hemispheric air. (3) No depression or distortion of the ventricle, but an absence of subarachnoid hemispheric air on one side associated with a contralateral ventricular enlargement. (4) Unilateral subdural hemispheric air with a contralateral ventricular enlargement. (5) Bilateral subdural hemispheric air with variable ventricular alterations, depending upon the amount and distribution of the air. In the final analysis, however, the authors conclude that a definite diagnosis of subdural haematoma can be made only by exploration.

#### 493 Healing of Peptic Ulcers

J. R. WYLIE (*Brit. J. Radiol.*, February, 1938, p. 90) divides gastric ulcers into superficial, anastomotic, deep, and penetrating, while in the evolution of duodenal ulcer he recognizes four stages, the last stage being that of penetration. The healing of the superficial gastric ulcer is indicated by a gradual disappearance of all obstruction, pain, and tenderness, and of the crater pool. During the healing of deep gastric ulcers the niche becomes gradually smaller until it finally disappears, converging rugae still remain and the pool disappears, while the tenderness gradually decreases. The spasm relaxes, although cicatricial hour-glass contraction persists. The penetrating gastric ulcer, in the author's experience, never heals under medical treatment. Carcinoma of the pancreas may develop in such cases, but the radiological recognition of this complication is extremely difficult. Deep or penetrating anastomotic ulcers heal very slowly. Berg's technique of gastroscopy should be especially useful in these cases both for the diagnosis and for the demonstration of the progress of healing. Healing will be indicated by the disappearance of the crater pool and the tenderness. The fistula does not close. The healing of deep or advanced duodenal ulcers is very slow, and the older the ulcer the more difficult is the healing. Healing is indicated by a gradual relaxation of the spastic deformity, a gradual disappearance of the pool and of the local tenderness, a restoration of shape of the duodenal cap except for some dimpling at the site of the ulcer, and finally by a gradual disappearance of all indirect evidence of ulceration. The penetrating ulcer never heals. It usually results in stenosis and is amenable only to surgical treatment.

#### 494 Osteomyelitis of the Vertebrae

J. R. McNURT (*Amer. J. Roentgenol.*, January, 1938, p. 52) reports five cases of osteomyelitis of the vertebrae and reviews the literature on the subject, of his own five cases three were acute and two chronic. The age incidence in a series of fifty-nine cases reported by Volkman was as follows: eighteen in the first decade, thirty-one in the second, seven in the third, one in the fourth and two in the fifth. 72 per cent of the cases were male. The organism in the vast majority of cases was the *Staphylococcus aureus* and in a large majority of cases the vertebral lesion was a metastatic infection from some discoverable source, such as a boil, carbuncle, etc. Fracture may be a predisposing factor. Osteomyelitis of the spine develops subperiosteally in adults and in young individuals as an epiphyseal sequestration. The tendency to new bone formation is characteristic and the lesion may first be noted on the radiograph as a rarefying or proliferative osteitis. The outline of a paravertebral abscess may be present early. The intervertebral disc may be

may not be involved although a uniform narrowing is often seen. The tendency to form new bone may prevent deformity of the spine but on the other hand in chronic mild cases with little pain marked deformity may occur before the patient seeks medical advice. The order of frequency of involvement of the different parts of the spine is lumbar dorsal, cervical and sacral. The posterior arches are more often involved than the body, except in the cervical region. The author discusses the differential diagnosis from tuberculous syphilitic and actinomycotic spondylitis, and gives the history of two typical cases.

495

## Klippel Feil Syndrome

A. H. LEMMERZ (*Med Welt* March 5, 1938 p 339) describes two cases of the Klippel Feil syndrome. The syndrome is caused by an arrested development of the middle part of the cervical spine, and is often associated with spina bifida torticollis or cranial and thoracic deformities. According to Feil the radiographic changes are produced by a trauma during gestation and the process is limited exclusively to the vertebrae. In one of the cases, that of a male aged 35, the first cervical vertebra was incomplete the second was hypertrophied the third and fourth were fused the fifth and sixth were small and the seventh was wide at its base and pointed in front. The bone structure of the affected vertebrae was irregular and osteoporotic. In the second case, that of a male aged 34 the posterior arch of the atlas remained open the axis was deformed and several other vertebrae were fused and rudimentary. The thoracic spine was scoliotic and there was incomplete fusion of the posterior arch of the seventh cervical vertebra. There was also a supernumerary rib at the transverse process of the first lumbar vertebra.

496

## Biological Measurement of X Rays

A. MARSHAK and J. C. HUDSON (*Radiology* December 1937 p 669) have investigated the effect of x rays of different voltages on the chromosomes of commercial onion seeds of the variety known as Ohio Yellow Globe. The seeds were allowed to germinate and seedlings with radicles of 1 cm. or longer were used for the experiments. They used three different kinds of irradiation—namely the first generated at 120 kV filtered through 5 mm of celluloid the second at 180 kV filtered through 0.5 mm of copper and 5 mm of celluloid and the third at 200 kV filtered through 5 mm of copper 0.9 mm of tin and 1 mm of aluminium. The ease of manipulation the low biological variability of the material used and the consistency of the response to irradiation make the method a very satisfactory one. The experiments have proved that the biological response per unit is independent of the wave length over the region studied. This is taken to indicate that the ion pair and not the quantum is the agent producing the effect observed.

497

## Treatment of Cancer

S. A. HEYERDAHL (*Norsk Mag Laegevidensk* April, 1938 p 395) gives an account of the activities of the Norwegian Radium Hospital since it was opened in May 1932, with accommodation for seventy one in patients. Of the in patients 62.6 per cent have been women 34.8 per cent men and 2.6 per cent children. The proportion of cases of benign tumours has risen from 7 per cent in 1932 to 15 per cent in 1937. The treatment has been by operation radium x rays or some combined method. In the two year period ending May 9 1934 1172 cases received treatment 1013 being cases of carcinoma. Twenty of the eighty three cases of sarcoma were symptom free more than three years after the institution of treatment. Of the 125 cases of cancer of the skin ninety were symptom free after three years and among the eighty three patients with cancer of the skin receiving treatment for the first time at this hospital there were as

many as seventy seven who were symptom free three years later. The results were practically as good for cases of cancer of the lip of which there were sixty five in all. Among the twenty six patients in this group who were treated for the first time at this hospital there were twenty-three who were symptom free three years later. Of the 183 cases of cancer of the breast forty three were symptom free after three years. The highest rate of recovery in this group was shown by the sixty-five patients treated by operation and then by x ray therapy after three years thirty six of them were still symptom free. Only five of the fifty four patients suffering from cancer of the rectum were symptom free after the same interval and not one of the eighteen patients with cancer of the prostate the eighteen with cancer of the oesophagus or the eleven with cancer of the stomach was symptom free after this interval.

498

## Arthropneumography

O. R. MAROTOLI and S. DE AZCUEAGA (*An Cirugia* December 1937 p 369) describe eight cases of injuries of the knee joint in which they adopted Bircher's technique of arthropneumography—that is x ray examination of the joint after the injection into the capsule of a positive (peribrodil etc.) or negative (oxgen nitrogen or air) contrast medium. This enables the cartilages and ligaments to be seen so that the condition may be diagnosed before operation. The injuries which include longitudinal and transverse tears or luxations of the internal or external semilunar cartilages were in five instances due to accidents on the football field.

499

## Irradiation of the Carotid Sinuses

F. VAN DOOREN and G. MELOT (*Arch Mal Cœur* February 1938 p 178) have applied x ray therapy to the carotid sinuses in a large number of patients suffering from high blood pressure. The irradiation of the sinuses gives rise to a general reaction. There is often a decrease of the maximal as well as of the minimal pressure, a slowing down of the blood flow and of the pulse and a vasodilatation. The biggest drop in the blood pressure occurs after the application of 30 r units but the effects of irradiation are only transitory.

500

## Profile Radiography of the Shoulder joint

H. POHL (*Scalpel Liege* February 26 1938 p 279) draws attention to the usefulness of the so called profile radiography of the shoulder joint for the differential diagnosis of the different traumatic affections of the shoulder. The radiographs are taken either from above the film lying in a curved cassette which is placed in the axilla between the arm and the thoracic wall or else from below the film resting horizontally on the shoulder. In either case a horizontal projection is obtained or the upper end of the humerus or the glenoid cavity of the acromion and of the coracoid process. In fractures of the surgical neck or of the diaphysis of the humerus the radiographs show the angulation and the overlapping of the fragments in the two planes and thus facilitate the reduction of the fracture. The radiographs may also show injuries to the coracoid process or to the tuberosities which may not be detected by the routine antero-posterior views.

501

## Biology of Fractional Dosage

J. BORAK (*Strahlentherapie* Berlin January 19 1938 p 63) discusses the biological foundation of the method of treatment of new growths with fractional doses of x rays. The epidermolysis observed after irradiation with fractional doses heals after a few weeks whereas the epidermolysis produced by a single large dose of x rays may lead to a necrosis of the irradiated tissues. In other words the difference between the radiosensitivity of the epithelium and the vascular endothelium is relatively

small when the irradiation consists of a single massive dose, but becomes very marked when the dose is divided into several fractions. The single epidermolytic dose is about 1 500 r units, but it may be increased two to two and a half times if given in fractions of 300 r units at intervals of twenty-four hours between successive applications. A dose three and a half times larger than the single epidermolytic dose leads to ulceration even when given in fractional applications. The histolytic dose for the vascular endothelium is about 2 500 r units as a single dose and two to two and a half times as large when given in fractional doses of 300 r units at intervals of twenty-four hours. According to Borak the tissues which behave like the skin epithelium belong to the 'multiform' tissues while the tissues which behave like the vascular endothelium belong to the 'uniform' tissues. To the first category belong the ovarian follicles, the seminal epithelium, the lymphopoietic system, the haematopoietic system, the hair follicles, the sebaceous glands, the epidermis and the stratified epithelia. In the group of 'uniform' tissues are included the vascular endothelium, the endothelium of the serous cavities, the fusiform connective tissue cells, the fixed connective tissue and glial cells, osseous and cartilaginous tissue, muscular tissue, nervous tissue and cylindrical epithelia. The tumour cells which originate from the 'multiform' tissues are on the whole radiosensitive. This group includes the lymphosarcomata, seminomata, basal cell carcinomata, trichopitheliomata, and epithelial carcinomata of the skin and mucous membranes. The tumour cells which originate from the 'uniform' tissues such as adenocarcinomata and the majority of sarcomata and of gliomata, are radio-resistant. Fractional doses are effective in the radio-sensitive tumours because the dose necessary to destroy the tumour cells is less than the dose which would damage irretrievably the vascular endothelium. Tumours which originate from the radio-resistant 'uniform' tissues, however, cannot be destroyed by x rays without simultaneous destruction of the blood vessels—that is, without producing necrosis.

## Obstetrics and Gynaecology

### 502 Treatment of Intra uterine Asphyxia

H. DORR (*Möchr Geburtsh Gynäk*, February 1938, p. 129) states that at Seitz's clinic the good effect of treatment of foetal asphyxia by pentamethylene-tetrazol (cardiazol) has been confirmed and no evidence found of an injurious effect due to premature stimulation of the foetal respiratory centre. Access to the foetal circulation is more quickly attained by intravenous injection in the mother than by direct injection into the foetal scalp or breech. Dorr found little or no effect from giving the mother intramuscular injections, or intravenous injections of less than 2 ccm. He records nine cases of severe impairment of foetal heart function (with notable slowing) in which intravenous administration of cardiazol was followed within twenty-five seconds by an improvement lasting four to five minutes and judged in some cases to have saved the child's life. There was no case of aspiration pneumonia.

### 503 Post-inflammatory Tubal Patency

C. DANIEL, D. MAURODIN and A. WANEFF (*Gynecologie*, January, 1938, p. 15) point out that tubal insufflation, which was first used as a diagnostic measure in sterility, is now applied, with success in 10 per cent of cases, as a therapeutic agent. The authors believe that correctly and cautiously used it is harmless even in acute and sub-acute inflammatory lesions; they did not find that insufflation disseminated infection into the peritoneum. Strict regard for a maximum pressure of 230 mm avoids the possibility of tubal rupture. The authors insufflated the

tubes of thirty-nine patients with inflammation of the adnexa in order to determine the proportion of cases in which permeability of the tubes remained. The operation was performed on the seventh to twelfth day after the end of menstruation in patients who had had inflammatory disease for from two weeks to six years. Permeability of the tubes was present in 43 per cent of the patients; it was present bilaterally in 14 per cent and unilaterally in 24 per cent. In 5 per cent insufflation effected patency of the tubes. In two cases of pelvic cellulitis following labour in one and abortion in the other, the tubes were found to be patent. The authors commend tubal insufflation in the diagnosis of sterility but advocate its use in conjunction with lipiodol injection and kymographic insufflation.

## Pathology

### 504

#### Sugar in Cerebrospinal Fluid

N. I. NISSEN (*Acta Psychiat Neurolog*, 1937, 12, 2, 173) discusses the value of estimation of the sugar in the cerebrospinal fluid in the diagnosis of meningitic conditions. Normally after the administration of 1 gramme of glucose per kilogramme of body weight the cerebrospinal fluid sugar rises by some 10 mg per 100 ccm after one and a half hours. In cases of acute infections and in meningitis this rise may be much greater, so that large doses of easily absorbed carbohydrates may be a source of error in the evaluation of cerebrospinal fluid sugar estimations. The normal value of sugar in the cerebrospinal fluid is approximately half that in the blood, and varies between 45 and 65 mg per 100 ccm. In cases of benign lymphocytic meningitis, acute anterior poliomyelitis, and encephalitis the values lie between 40 and 65 mg per 100 ccm or may be higher. In tuberculous meningitis lowered values are always found and only in the earliest stage may the sugar content be normal. In purulent meningitis the values are usually below 40 mg per 100 ccm. The changes in the cerebrospinal fluid sugar are quite independent of the size and type of the cell increase, and also of the total protein, but they are parallel to the changes in the chlorides. The mechanism of the fall in purulent meningitis is not known. It is not dependent on the cell increase; this may be considerable and the sugar normal, nor on the presence of bacteria. It may be due to increased sugar consumption by the inflamed meninges or to its failing to pass through the choroid plexus. High values for sugar in the cerebrospinal fluid do not arise from diseases of the central nervous system, but may be found in acute general infections, such as pneumonia.

### 505

#### Chemotropism of Normal Skin

D. SILVERMAN (*Arch Pathol*, January, 1938, p. 40) describes experiments demonstrating the presence of chemotropic substances in normal epidermal tissues. Pulp prepared from normal skin attracted leucocytes. If the skin were well extracted in hot water the pulp prepared from it had lost its chemotactic power, but this could be restored by soaking the extracted skin in the concentrated extract. Kaolin also could be made positively chemotactic by soaking it in the concentrated extract. The chemotropic substance was therefore water soluble and heat-stable; it did not contain carbohydrate or histamine but did give reactions for protein and free amino acid groups. Experiments with agar and kaolin showed that physico-chemical factors played no part in the chemotaxis. In non-infected injured skin chemotaxis of leucocytes therefore depends on substances such as those demonstrated. Since bacterial substances are also chemotactic, chemotropism in infected skin might depend partly on bacterial substances and partly on substances derived from the injured tissues.

## Pure, active, comfortable and inexpensive

An increasing tendency is shown to claim a very high purity and remarkable hæmopoietic potency for injectable fractions of liver

Independent chemical research in stringent conditions of clinical test have maintained the place of Organon's PERNAEMON FORTE in this field

PERNAEMON FORTE, now a clear solution provides a medium for the therapy of Pernicious Anæmia as pure as active as comfortable and as inexpensive as any available.

## Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e., 1-ounce, provides 200 International units of Vitamin B<sub>1</sub>, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B<sub>1</sub> "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B<sub>1</sub> daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B<sub>1</sub> potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

# BEMAX

A unique natural source of accessory nutritional factors.

Vitamin B <sub>1</sub> — 200 I.U. per ounce	Vitamin E — 400 I.U. per ounce
Vitamin B <sub>2</sub> — 10 I.U. per ounce	Phosphorus — 50 mg. per ounce
Vitamin A — 100 I.U. per ounce	Magnesium — 50 mg. per ounce
	Iron — 3 mg. per ounce
	Copper — 0.5 mg. per ounce

## VICTOR ANNOUNCES An Electric Stethoscope —THE CARDIOFONE

Every physician who uses a stethoscope will be intensely interested in the new VICTOR Cardiofone. A precision instrument, built to incorporate the latest developments in the science of acoustical amplification, the Cardiofone is an instrument of value to everyone engaged in the practice of medicine.

To those physicians who because of the specialized nature of their work feel that the ordinary stethoscope imposes limitations, the advent of the Cardiofone will be particularly welcome because this sensitive instrument opens up a whole new field of diagnosis by auscultation.

Send the coupon for the whole story of this latest addition to the physician's armamentarium. The free booklet will be sent immediately and without obligation.

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in September, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax)

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances

Opportunities are available for officers on the permanent list for post graduate study, to specialise, to take higher examinations and to obtain further qualifications

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy Admiralty, S W 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than 31st August, 1938

# GLASGOW POST-GRADUATE MEDICAL ASSOCIATION

POST-GRADUATE TEACHING in Glasgow during the Summer of 1938 comprises principally

- A General Practitioner's Medical and Surgical Courses from July 18th to August 27th, and
- B Clinical Assistantships in General and Special Hospitals

Syllabuses and any other information may be had on application to the Secretary, Post Graduate Medical Association, The University, Glasgow

## UNIVERSITY OF LONDON KING'S COLLEGE

### FACULTY OF MEDICAL SCIENCE

The Medical Faculty at this College of the University gives instruction in the subjects of Medical Science for all the usual Pre-medical and Intermediate Examinations in Medicine, Surgery and Dentistry. Through the four associated hospitals, Students of the College have clinical facilities of over 1,000 beds.

The Medical Faculty of the College provides a general University education in touch with other faculties,atives of which medical students are permitted to attend. There are many College societies, clubs and functions in which student of all Faculties have opportunity of meeting each other. The College has an excellent athletic ground at Mitcham with a new and well equipped pavilion.

The first year subjects are taught in the large Department of the Faculty of Science and those of the Second and Third Years in the new Medical Department. This includes the Hammersmith Department of Anatomy and an extension to the Department of Physiology recently completed at a cost of £10,000. These new buildings and those of recent years provide the College with a completely new and modern Medical Department which embodies the newest ideas in laboratory construction and equipment.

Valuable scholarships and prizes are awarded on the results of examinations held annually.

The Hostel for men students (The Phoenix, Champion Hill S.E. 15) contains accommodation for 80 students. The Hostel for women students is at 55, Queensborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean of the Medical Faculty or to

# INDIAN MEDICAL SERVICE

## RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 25 years of age and who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

### CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres, to provide for the medical needs of Civil Officials and for general medical administrative purposes, to specialist (for example public health and bacteriological) services, to research posts and to professorships at the Medical Schools.

### RATES OF PAY

22		1500	40	1830
23		1500	40	1830
24		1500	40	1830

\* A—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.

(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1.00 per mensem (basic) plus Rs. 0.40 per month overseas pay.

At the end of the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rate of pay are also attached to the numerous administrative appointments given to officers in both branches of the Service.

### ANTEDATED IN COMMISSION

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized

hospitals may be seconded in those posts for a period. The maximum period of antedate secondment or antedate and secondment combined admissible under this paragraph is limited to 18 months.

### OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

### PRIVATE PRACTICE.

With the exception of Administrative Officer, military or civil and officers holding certain special appointment, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

### LEAVE.

Leave can be taken at reasonable intervals and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed twelve months in all during an officer's service may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave study allowance at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe and £1 10s. a day in the United States of America and Canada is granted to an officer in addition to ordinary rates of leave pay.

### PENSIONS.

The rates of pensions are as follows —

After 17 years' service for pension	Per annum
18	£372 0s.
19	£400 0s.
20	£428 0s.
21	£465 0s.
22	£502 0s.
23	£539 10s.
24	£576 10s.
25	£614 0s.
26	£651 0s.
27	£697 10s.
28	£744 0s.

There are additional pensions ranging from £65 to £200 per annum for officers who have held administrative appointments.

### PASSAGES

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of travelling charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

### INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months prior to their embarkation for India on first appointment. Information as to the rates of pay and leave during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, SW 1. The Selection Committee will meet at the India Office about July 26th next, and the selected candidates unless seconded for hospital appointments, will be required to join a course of instruction commencing about September 1st prior to sailing for India in December 1938. Applications should reach the India Office as soon as possible.

# DERBYSHIRE COUNTY COUNCIL

# WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD

## APPOINTMENT OF MEDICAL SUPERINTENDENT

### STORTHES HALL MENTAL HOSPITAL Kirkburton near Huddersfield

The West Riding of Yorkshire Mental Hospitals Board invite applications from duly qualified medical practitioners for the appointment of a Medical Superintendent in their service at the Storthes Hall Mental Hospital Kirkburton near Huddersfield.

Candidates must have had previous experience as the Medical Superintendent or Senior Medical Officer of a Mental Hospital.

The person appointed will be required to devote his whole time to the duties of the office and to act in conformity with the provisions of the Lunacy and Mental Treatment Acts and the general rules and regulations of the West Riding of Yorkshire Mental Hospitals Board.

The minimum and maximum salaries fixed for the position are £1000 and £1400 the annual increments being £50. The commencing salary to be paid will within these limits be according to qualifications and experience and is entirely at the discretion of the Board.

The person appointed will be provided with an unfurnished house which will be deemed to be valued for superannuation purposes at the sum of £50 per annum. There are no other emoluments attached to the position. The salary and value of the unfurnished house will be subject to deductions under the Asylums Officers Superannuation Act 1909.

Application must be made on a form which can be obtained together with any other particulars from the undersigned to whom the completed forms should be returned not later than June 30th 1938. Canvassing in any form will be a disqualification.

Board Offices G LESLIE BANNER  
Victoria Chambers Clerk of the Board  
Wood Street  
Wakefield (P.O. Box No. 23)

# Femergin

ergotamine tartrate

**AFFORDS COMPLETE RELIEF FROM PAIN AND OTHER SYMPTOMS IN A HIGH PERCENTAGE OF MIGRAINE PATIENTS**

The experience of the past few years has demonstrated fully the value of hypodermic injection of Femergin (ergotamine tartrate) in the relief of an attack of migraine

—Medical Annual 1937, p 308

Certain recent work goes to confirm the view that the headache of migraine is associated with a vasodilatation of the meningeal vessels. First we have the action of ergotamine tartrate. This drug was introduced as a remedy for the pain of migraine a few years ago and experience has shown it to have a most potent action in cutting short an attack.

—Glasg Med J 1937, 10 214

Because of the constancy and character of the relief obtained from 1042 headaches in eighty nine sufferers of migraine after the administration of ergotamine tartrate I recommend its use for the termination of these attacks and believe that the drug is a valuable addition to medical therapeutics.

—J Amer Med Ass 1936, 107, 1212

Supplied in Ampoules  
Tablets and Solution

## Appointments for Medical Officers in The ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force

Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study.

Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission, up to twelve months, is allowed for appointments held at approved hospitals.

Fuller information can be obtained from The Director of Medical Services, Air Ministry, Kingsway, London

## For Analgesia in Midwifery

The "AUTOGESIA"  
SELF-ADMINISTERED  
GAS AND AIR APPARATUS  
Patent No. 463492

APPROVED BY THE CENTRAL  
MIDWIVES BOARD  
for use of MIDWIVES

A simple but efficient portable apparatus which relieves pain without loss of consciousness. Automatic in action it delivers a fixed percentage of gas and air and the patient cannot receive pure nitrous oxide or too high a pressure of gas.

Size - 16 x 9½ x 9½ ins  
Weight complete - 28 lbs

PRICE - 12 guineas  
(without gas and cylinders)

NEW — COMPACT — COMPLETE

# GIFFORD'S Textbook of Ophthalmology

**Practical Ophthalmology**—that is exactly what this book is devoted to those *clinical* facts of diagnosis and treatment that are so vitally important to *practicing* every physician—Specialist and General Practitioner alike.

Dr Gifford has discarded unessentials. He has left the bare bones. He has no rote cases, symptoms, methods of examination, diagnosis and *both medical and surgical* treatment. He has no language or practice.

Dr. Gifford tells you *what* to look for *how* to find it and *where* to find it. He points out anatomical and physiological facts that will assist you in understanding the *why* of the disease and conditions of the eye.

You will find details of manual, in numerical and letter symbols. The special emphasis on *Evolutionary Symptoms in General Diseases* and 44 papers on the various procedures employed to find errors and how to correct them.

You are told exactly what therapeutic measures are indicated and then, in detail, on administration. The use of solutions, ointments, irrigations, injections, heat and cold, premedication, etc. are all included while operative technique is vividly described and pictured.

The entire book is beautifully illustrated with many of the pictures in the book.

By SANFORD L. GIFFORD, M.A., M.D., F.A.C.S., Professor of Ophthalmology, Northwestern University Medical School. 492 pages, fully illustrated. Cloth \$18.00 net.

## Herman's Practice of Urology

**Just Ready**—An up-to-date presentation of the latest advances in all subjects of urology. There is special emphasis on practical essentials as they relate to diagnosis and treatment.

*'Can you read this?'*  
says Mr. Therm

It's one of  
my O.D.B. advertisements'

O.D.B. means the Order of the Daily Bath. It's Mr. Therm's genial way of advocating greater personal cleanliness and freshness by taking a bath every day. Have you seen any of these advertisements in the daily press? If so, Mr. Therm hopes you approve of their message.

Mr. Therm is treating the subject with restraint, but he is making the right points. That a daily hot bath keeps the skin clean and obviates some of the disorders of the body. Mr. Therm would be delighted if he felt that Doctors were giving him their important backing.

**O.D.B. is the ORDER of the DAILY BATH**  
the slogan used in a series of national press advertisements

## The Modern Shorts for the sedentary man

The new, close-fitting Linia Shorts are a boon to the man leading a sedentary life. Made of elastic tricot, they exert a gentle beneficial massage on the abdominal area and give firm support. They are designed for wear instead of ordinary under-pants, and are light, easily laundered, porous and hygienic.

A development of Linia Shorts is Linia Reinforced Shorts which have a panel of finer elastic over the abdomen for better support and control where there is a tendency to obesity.

### You can order by post

## CARBOHYDRATES IN THEIR MOST EASILY ASSIMILATED FORM

**ideal milk modifier for  
bottle-fed babies**

PHYSICIANS all over the country have found a satisfactory solution to the problem of supplying easily assimilable carbohydrates to infants and children in Karo, a balanced blend of natural sugars.

Over 300 letters recently received from physicians confirm the good results of using Karo as an addition to the diet of premature or bottle-fed infants and of children suffering from marasmus, acidosis, cyclical vomiting, diarrhoea, and all kinds of digestive and nutritional disorders.

Karo is recommended as a means of modifying cow's milk and milk powders for normal artificially-fed infants, and is particularly useful in all those cases where ordinary sugar does not give satisfactory results.

*Within the reach of poor people*

Karo is sold at a price that is within the reach of poorer patients. A 1lb tin, costing 1/3 provides a ten days' supply for a three-months-old baby—a cost of about 1½d a day. The price of the 2lb tin is 2/-.

## TOXAEMIA

Many patients suffer from the metabolic and physiologic deficiencies which SALVITAE is designed to correct. They are virtually human septic tanks, their blood and tissues charged with poisonous products derived variously from the retained wastes of catabolism from a chronically overloaded colon and other foci of infection

Professional samples and  
literature gladly sent on  
request

# SALVITAE

SALVITAE takes care of the bowel stasis (and concurrent putrefaction or fermentation), the elimination of nitrogenous and toxic wastes from the kidneys and the neutralization of excessive acidity. With these major instigators of a toxic condition rendered inoperative, the patient must necessarily evince improvement.

COATES & COOPER LTD, 94, CLERKENWELL ROAD, LONDON, EC1

## RELIEF OF ECZEMA ★

We have on record many cases where persistent eczema which had proved refractory has yielded readily to Sphagnol Peat Ointment. It is commonly known that difficulty in obtaining rapid healing of eczematous conditions is often due to interference by the patient provoked by the intensive irritation. Particularly is this so with children. Sphagnol Ointment soothes from the first application giving instant

relief from itching. At the same time the healing peat distillates which it contains promote the growth of clear healthy skin.

In case you have had no personal experience of Sphagnol we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd Dept BM J 7 21 Bush Lane London EC4

## Modern Iron Therapy

Iron Jelloids are an elegant and reliable means of administering the proto-carbonate of iron. The preparation has none of the disadvantages of Pil. Bland. The iron content remains fresh and unoxidized indefinitely and

interacts with aroid.

Iron Jelloids are highly effective in the treatment of a chlorhydric anaemia and indeed in all the simple anaemias in which massive iron is indicated.

# Iron Jelloids

You are cordially invited to apply for samples for clinical test.

# ACRIFLAVINE 'B.D.'

*The antiseptic of universal application*

## In Surgery

Acriflavine 'B.D.' provides an effective general bactericide and antiseptic for use in surgery; it is particularly valuable in ophthalmic work on reason of the fact that its solutions of a strength sufficient to be actively antiseptic are non-irritating; indeed, for this purpose it has been reported that *it is nothing to touch it*.

## In Medicine

Acriflavine 'B.D.' is unequalled in its value in the irrigation treatment of gonorrhœa, whilst in such local septic conditions as eczema impetigo, pediculosis, pemphigus neonatorum and ulcus molle, also in oral sepsis its application produces remarkably beneficial results. More recently, considerable success has followed the intravenous injection of solutions of a specially-purified Acriflavine 'B.D.' in such internal infections as meningococcal septicæmia.

## The Conservative Treatment of Sinus Disease

# ARGYROL

BRIND SILVER NITELLIN

The increasing popularity of the Argyrol pack treatment introduced by Dowling (of Albany) and recommended by Halstine (Chicago) and many others is due to the striking results that have followed the employment of this technique, in children as well as in adult.

The tampon or pack treatment 'provide drainage and ventilation to the sinuses improves the tone of the mucous membrane and subjacent erectile tissue and make possible the avoidance of a large percentage of the operative procedure within the nose or upon the sinuses (Dowling). Argyrol is particularly effective in all mucous membrane inflammations because of its unique sedative, detergent and mildly astringent properties. Its use in sinus disease is

therefore preferred for tampon therapy by most authorities in this field.

It should be emphasized that Argyrol is not just another 'mild silver protein'. It is different because its constituent elements are different. Argyrol is in a class by itself—*argentis*. It has never been duplicated and it is the only silver salt which retains its mildness in increased concentrations. In testimony on having the name ARGYROL on all solutions ordered or prescribed will insure the clinical results you expect.

## In Pruritus Ani,<sup>1</sup> Anal Fissure,<sup>1</sup> Pruritus Vulvæ,<sup>1</sup> and Lower Abdominal Pains originating from the Cervix Uteri<sup>2</sup>

Proctocaine is a lasting, non toxic, local anæsthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of A.B.A. Proctocaine is a combination of oil soluble anæsthetics of low toxicity. These are combined so as to produce *immediate local anæsthesia* which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil soluble ingredients.

The advantages of Proctocaine over other solutions have been found<sup>1</sup> to be as follows

- 1 Its effect is almost certain
- 2 It produces anæsthesia or hypo anæsthesia for periods varying from 7 to 28 days or longer
- 3 The relaxation which it produces in the anal musculature is much greater and more prolonged
- 4 It is comparatively non toxic, injection of 20 to 30 c cm producing no general effect
- 5 Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly
- 6 Its injection is painless if made slowly
- 7 In no case did it produce severe after pain

## LIVOGEN

### *In Convalescence*

A well-known physician stated recently that he prescribes Livogen invariably because it produces a rapid marked effect in convalescence following severe illness. The patient's appetite is stimulated and with the accompanying renewed vitality and re-instated normal digestive processes, such signs as depression and inertia disappear and the patient recovers natural vigour and enjoyment of life.

# OVALTINE

## BEFORE AND AFTER OPERATIONS

THE use of Ovaltine before a major operation is of great service in helping to build up the system against the strain involved by operative interference. In abdominal cases especially where a light and unirritating diet is necessary the use of Ovaltine alone for a few days before the operation will be found sufficient to maintain the patient's nutrition at a sufficiently high level.

After severe operations the regular use of Ovaltine is of the greatest service on account of its bland nature, its ready digestibility and its highly nourishing and sustaining properties.

Ovaltine is a complete food composed of fresh full cream milk, eggs and malt extract in the form of crisp granules which dissolve readily in milk to form a delicious beverage acceptable to the convalescent patient.

## The respective merits of DETOXICATED and TOXIC VACCINES

The obvious advantage of Detoxicated Vaccines is that large doses can be administered without causing serious reactions. This is of great value in the treatment of cases where any given bacterial disease is already established. In such cases toxic vaccines are apt only to aggravate the symptoms whereas moderate doses of the appropriate detoxicated vaccine can be given safely without further aggravation of the disease.

We have always upheld the superiority of detoxicated vaccines but some authorities prefer the toxic varieties because they believe that it is important to obtain more or less marked reactions in order to produce a satisfactory immunity.

The toxic vaccines have the advantage of cheapness. The detoxicated vaccines are more expensive for the obvious reason that the dosage is nearly one hundred times greater so that much larger quantities of bacteria are used in their preparation.

We supply both the detoxicated and the toxic varieties of vaccines in order to cater for the two different schools of thought in this matter. A booklet giving details of our full range of Detoxicated and Ordinary Vaccines, will gladly be supplied on request.

## Pleasure Cruises . . .

3rd March, 1938

Messrs Kaylene, Ltd, Waterloo Road London, NW 2

Dear Sirs,

I have to thank you for the samples of KAYLENE and COLONOL LIQUID PARAFFIN, which arrived this morning.

It may be of interest to you to learn that KAYLENE-OL is an admirable prophylactic for the dysenteries and other intestinal infections common in hot countries. I invariably prescribe it to patients who are going for a holiday in the countries around the Mediterranean littoral, or pleasure cruising.

I think it probably acts by preventing injury to the intestinal mucosa in patients who evaporate a lot of fluid from the skin and, in the case of amoebic dysentery, by hindering the *Entamoeba histolytica* from entering the crypts of Lieberkuhn by occluding them with an oily film.

Patients who use it systematically every day as a prophylactic remain singularly free from the numerous troubles arising from the exuberant bacteriological flora of the intestine which is the rule in hot countries.

I am guided in my opinion largely by personal experience. I have had dysentery seven times and each time was definitely associated with the running short of my usual prophylactic dose. I do not know of anybody ever contracting dysentery while maintaining the regular daily prophylactic dose of KAYLENE-OL.

Yours faithfully,  
Signed

, M D

# Ergoapiol (Smith)

## A Menstrual Regulator...

When the periods are irregular, due to constitutional causes, ERGOAPIOL (Smith) is a reliable prescription. Containing apiol (MHS special) together with ergot, aloin and oil of savin of the highest quality, this preparation effectively stimulates uterine tone and controls menstrual and postpartum bleeding.

In cases of Amenorrhea, Dysmenorrhea, Menorrhagia and Metrorrhagia, Ergoapiol serves

as a good uterine tonic and hemostatic. Valuable in obstetrics after delivery of the child and for the menstrual irregularity of the Menopause.

Prescribe 1 to 2 capsules 3 or 4 times daily. Supplied only in packages of 20 capsules. Literature on request.

As a safeguard against imposition the letters MHS are embossed on the inner surface of each capsule visible only when the capsule is cut in half as shown.

# VICHY-CELESTINS

THE WORLD RENOWNED  
FERMENTATIVE

NATURAL MINERAL WATER  
DYSPEPSIA

When the secretion is vitiated in quality and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.) which not only irritate the mucosa but further, after their passage into the intestine,

NATURAL VICHY SALT for  
Drinking and Baths

become absorbed by the lymphatics and swept into the circulation. Vichy-Célestins, by its slightly stimulating action, clears out the stomach and thus avoids stagnation and consequent fermentation. As in addition to doing this it modifies stomatal metabolism the secretions return little by little to their normal physiological condition.

## FOR SUBNORMAL HÆMOGLOBIN PRODUCTION

### *Liver Extract with IRON plus COPPER*

Cofron Elixir (Abbott) supplies Whole Liver Extract Iron and Copper in definite, standardised proportions. It is indicated for the treatment of mild anemias and for use in many non-specific conditions in which there is a decreased red cell count or a lowered haemoglobin percentage. The product is particularly suitable for general use as an iron tonic or to hasten restoration of normal red cell values following illness that has resulted in anemia. Each fluid ounce of Cofron Elixir represents Fresh Liver 10 gms (1½

oz.) Iron 66 mgms (1 gr) (the equivalent of 6 grs. of iron and ammonium citrate B.P.) and Copper 2.66 mgms (1/25 gr). The liver extract contains the factor or factors necessary for the maturation of red blood corpuscles and in addition supplies appreciable amounts of vitamins B<sub>1</sub> and B<sub>2</sub> which

supplement the patient's daily intake of the factors and thus contribute to improved appetite. Iron is essential in the synthesis of haemoglobin while much clinical evidence indicates that copper aids in the full utilisation of iron by the body. Cofron Elixir is supplied through pharmacies in 12-oz. and 80-oz. bottles. Descriptive literature and a free sample will be sent upon request.

#### COFRON CAPSULES

For Severe Secondary Anemias  
Supply about twice as much liver extract as Cofron Elixir in proportion to their copper and iron content. In bottles of 50 and 100 capsules

# CRUNCHY FOODS AND SALIVATION

---

The proper insalivation of food is held by many physiologists to be an important factor in digestion on account of the action of ptyalin in partially converting starch

For this reason they consider that the normal diet should include a proportion of hard, dry foods, which demand thorough mastication and thus induce copious salivation.

Ryvita is a daily bread of hard, friable consistency. It therefore supplies a valuable factor which civilised dietaries too often lack. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

## B.D.H. VACCINES

The special rubber-capped 3 c.c. vials in which B.D.H. Vaccines are issued are appreciated by all physicians who have employed them in the course of practice, on account both of convenience and economy. They find that the usual wastage associated with the use of a fresh 1 c.c.

ampoule for each injection in a course comprising from four to six injections is avoided. By the use of B.D.H. Vaccines there is thus effected a saving both in time and expenditure.

The metal dust-cap (which is removed before the needle of the

syringe is inserted through the rubber cap and is replaced after the vaccine has been withdrawn and the rubber cap swabbed with disinfectant) serves to maintain the sterility of the rubber cap, keeping the whole vial ready for use on the next occasion.

*A specimen 3 c.c. vial containing any one of the B.D.H. Vaccines will be sent on request.*

# TWO CHOLINE COMPOUNDS FOR PARASYMPATHETIC STIMULATION

## 'DORYL'

(Carbaminoyl-choline chloride)

A stable and potent choline ester greatly superior to acetyl choline. Very effective by injection in post-operative retention of urine and intestinal atony, paralytic ileus etc. Oral doses possible and successful in irritable hearts, paroxysmal tachycardia (with compensation) and anxiety neurosis. Raynaud's disease and certain other vascular diseases have benefited by Doryl administration. In ophthalmology, a special Doryl solution has proved useful in glaucoma. For tobacco and other amblyopias the tablets have been found valuable. A special solution is also available for the treatment of ozaena.

TABLETS — AMPOULES — SOLUTIONS

## 'MECHOLYL'

(Acetyl- $\beta$ -methyl-choline chloride)

Mainly recommended for use by iontophoresis, and has proved very effective in treating arthritis especially of the rheumatoid type, peripheral vascular diseases such as Raynaud's disease and scleroderma, thrombo-angitis obliterans, and ulcers. A 0.1-0.5% aqueous solution with a strength of current of 20-30 mA is advised.

CROOKES' KAOLIN has achieved a great measure of success in all forms of intestinal toxæmia. It exercises the effect of adsorbing poisons, especially bacterial toxins, and of forming an adherent coating on the bowel wall protecting the surface from irritant particles and digestive juices in ulcerated conditions.

In conditions of ulcerative colitis and chronic conditions of the intestines where there is a large excess of the coliform type of bacillus, Crookes Lacto-Kaolin is more especially recommended owing to the properties of the lactose constituent.

Both products are superior to any other medicinal kaolins on the market in respect of the fineness of division of the kaolin particles. It is upon this that the adsorptive power depends.

*A major operation in progress in the operating theatre of a London Hospital*

## ANTISEPTIC PROTECTION IN THE THEATRE

THE greatest danger in any operation is the risk of introducing bacterial micro-organisms into the system. Because of this, elaborate precautions are taken in the operating theatre to prevent infection. Modern antiseptic methods have succeeded in eliminating sepsis—once the surgeon's greatest fear and problem.

Risks of infection in everyday life, though less serious, are more numerous. In ordinary hygiene prophylactic measures cannot, of course, take the elaborate lines of the operating theatre, but fortunately the simple use of soap and water usually affords adequate protection against most forms of infection. But the degree of protection naturally depends on the antiseptic, antipruritic and germicidal qualities of the saponifying agent.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for purposes of general protection for over 70 years. It has substantial

antiseptic and antipruritic qualities, and to-day, besides being specified by leading bacteriologists as the ideal everyday safeguard against infection, is used (according to the 1932 investigation of the Institute of Industrial Psychology) by doctors themselves more than any other brand of toilet soap. Wright's is the *only* soap to contain 'Liquor Carbonis Detergens' (Wright's), the valuable therapeutic used and recommended by eminent dermatologists. You can have every confidence in using Wright's in *your* practice and recommending it to *your* patients.

INDICATIONS FOR 'SANATOGEN'

No 3

# Diabetes

Chemical experience has now definitely established that diabetes can be traced to an intricate biochemical disturbance of metabolism, which extends far beyond the limits of the carbohydrates. From this it follows that the state of the nervous system plays a most important part—nervous complications of the disease are common and the harmonious balance of endocrine action, which is necessary for a normal carbohydrate metabolism, is, of course, controlled by the nervous system.

The tonic effect of 'SANATOGEN' upon the nerves has, as many clinical records show, conferred definite benefit in the treatment of diabetes. This highly concentrated food contains .95 per cent pure milk casein with 5 per cent sodium glycerophosphate. It is very easily digested. Literature giving detailed reports on its effect in diabetes will be forwarded, free of charge, on request.

"I have now completed my test of 'Sanatogen' on diabetic patients. A man of 28, who has had Diabetes for 12 years has been sugar-free for 8 weeks, in spite of the fact that I have gently lowered his Insulin weekly for this period. A man of 55 is practically sugar-free for 8 weeks, although as above. A woman of 48 has reduced her sugar from 2 and 3 per cent to 5 per cent during the time she has been taking 'Sanatogen'. In my own case, I have been able to reduce my daily Insulin by 20 units, and I now average from 5 per cent to 1 per cent sugar. I have pleasure in testifying to the efficacy of 'Sanatogen' for Diabetes."—M R C S, L R C P

THE 'STONE OF THE MEASLES' WITH CUP MARKINGS A SCOTTISH MAGICO-MEDICAL MONUMENT—This object associated with the cure of disease from time immemorial fell into disuse only during the last generation. In the opinion of most archaeologists the cup-markings date it back to the neolithic phase. It has evidently been transported from a considerable distance to the middle of a field where it now stands. Its artificial cavity holds about two quarts of water. Rain-filled from heaven it acquired powerful healing qualities and children suffering from measles were brought from far and near for cure. Before drinking the water the patient had to pass round the stone from left to right which may represent an act of sun-worship.

DATE The chronological date is undetermined, but the phase is neolithic.

### LECTURE II

#### Pharmacology of Carbaminoyl-choline

Carbaminoyl-choline was introduced by Kreitmair (1932) working in the pharmacological laboratories of Merck of Darmstadt. He considered that it excelled acetylcholine in many ways appearing to be more powerful and active at doses usually associated with hormones or vitamins. It is much more stable than acetylcholine in solution withstands boiling and is active even when administered in the digestive tract.

Stronart and Simonart (1934) showed that it is less active than acetylcholine and that its comparative stability is accounted for the apparent greater activity as a parasympathetic stimulant but that it is stronger in its nicotine-like properties. Kreitmair (1932) worked with dogs and cats and showed that in general it has the same qualitative effects as acetylcholine acting typically as a stimulant of parasympathetic stimulation and that atropine inhibits its effects. Veltin (1933) studied its action on the stomach noted contraction of the muscle and an increased flow of gastric juice and found that it induced contractions in the puerperal uterus of cats. He concluded that there is no accumulation or habituation in cats on a daily dose over long periods but that injections of large doses repeated twice daily for several days caused paralysis and death in some cats though not in others. At necropsy no reason for death was found. In man E. A. Starr (1937) has observed evidence of accumulation with subcutaneous injections and found it necessary to lower the dose. Noll (1932) studied the effect of subcutaneous injections and of oral and rectal administration in cats following a barium meal and demonstrated a powerful action on the musculature of the intestines in two and a half hours. He noted great salivation and an increase in the flow of gastric juice. Dautrebande and Marechal (1933) gave 0.01 mg per kilogramme of body weight to dogs and noted tachycardia and a fall in blood pressure followed by bradycardia and also stimulation of respiration. Dautrebande (1933) gave the same dose to cats by intracarotid injection and concluded that the

tachycardia is due to a reflex from the carotid sinus and that the carotid sinus is responsible for the immediate stimulation of respiration and also for a secondary stimulation of the time of the fall in blood pressure. Destree (1937) gave 0.125 mg per kilogramme to dogs with Pavlov fistula and found that it produced an increase of total and free acid and of mucus in the gastric secretion. Atropine prevented this action.

In so far therefore as its effects on animals are concerned carbaminoyl-choline differs from acetylcholine mainly in its greater stability so that prolonged effects can be obtained by subcutaneous injection and even by oral or rectal administration.

#### Actions of Carbaminoyl-choline in Man

Dautrebande and Marechal (1933) reported that the administration of 0.1 mg to man by intravenous injection produced a fall in blood pressure a feeling of heat dilatation of superficial vessels increased activity of movements within the abdomen salivation and lacrimation. They also found that the intramuscular injection of 0.2 to 0.3 mg caused a fall of blood pressure that persisted for twenty to forty minutes.

#### INTRAVENOUS INJECTION

In 1932 E. A. Carmichael and I began observations on the effects in man of intravenous injections. These preparations were kindly supplied by Merck and Co. and consisted of a solution of carbaminoyl-choline chloride in sterile ampoules (1 c.c.m. containing 0.1 mg) under the name of lentin and later of ampoules containing 0.25 mg in 1 c.c.m. under the name of dorvi. We gave fifty-eight injections to eleven subjects—patients in hospital convalescing from acute infections or admitted for chronic conditions such as osteo arthritis tabes dorsalis etc. Starting with a dose of 0.01 mg the dose was increased until a definite effect on the pulse rate or blood pressure was obtained. The pulse rate for each three second period was calculated from a continuous polygraphic record and blood pressure readings by the auscultatory method were taken as often as possible. Typically a fall of both systolic and diastolic blood pressures occurred accompanied by a rise of pulse rate ten to twenty seconds

\* The Croonian Lectures delivered before the Royal College of Physicians of London on May 24, 26 and 31 1938. Lecture I was published on June 11 at page 12-9.

following the injection Fig 4 shows the characteristic effect on the pulse rate. The blood-pressure readings are too inaccurate to be worth recording, but falls from a systolic of 130 mm Hg to 90 mm Hg and from a diastolic of 80 mm Hg to 60 mm Hg were commonly noted. The maximum effect on both blood pressure and pulse rate was reached in from thirty to forty seconds following the injection, and both had returned to the previous level at the end of sixty seconds. These effects appeared with a dose of from 0.03 to 0.05 mg. The previous injection of 1 mg of atropine sulphate prevented the fall of blood pressure and the rise of pulse rate. In one patient little if any rise of pulse rate was obtained even when other symptoms occurred, and this was noted also following injections in patients who had previously reacted typically to smaller doses. On two occasions only did the pulse rate fall, and in both instances the blood pressures dropped as usual and typical rises of pulse rate occurred in the same patients on other occasions. In neither instance was the fall followed by a rise of pulse rate.

The effect of the intravenous injection of carbaminoylcholine on the pulse rate in producing a rise and only

Fig 4

occasionally a fall differs, therefore, from that of acetylcholine, which produced in nearly every instance a fall followed by a rise.

Other symptoms that accompanied the rise of pulse rate were flushing of the head and neck, a feeling of heat throughout the body, a sensation of fullness in the head or headache, coughing, and a feeling of tightness in the throat or upper thorax. These symptoms were transient, variable in degree, and lasted only a few seconds. Less constantly, sweating, salivation, and lacrimation occurred. If the injections were repeated after a few minutes the effects were the same, but after a number of injections had been given a few patients complained of abdominal unrest, and two of them defaecated shortly after the termination of the observations. In four patients effective injections were repeated following the intravenous injection of 1 mg of atropine sulphate, and in each the symptoms were entirely prevented or very greatly diminished in intensity.

Three patients received doses of 0.02, 0.05, and 0.25 mg injected into the femoral artery. A slight flush occurred in the distribution of the femoral artery, but no flushing or other symptoms in the rest of the body. In these doses it had much less effect by this route than we had obtained with doses of acetylcholine of 5 to 25 mg, but we hesitated to use larger amounts because of the stability of this ester.

#### SUBCUTANEOUS AND INTRAMUSCULAR INJECTION

From these results it does not appear that carbaminoylcholine offers any advantages over acetylcholine itself for therapeutic purposes if given by intravenous injection, the effects being extremely transient when safe doses are employed. By subcutaneous or intramuscular injections conspicuous and sustained effects are obtained and during the past five years I have been able, with the help of

different colleagues, to study the effects on more than twenty-five patients. The results vary considerably from subject to subject, and in the same subject from day to day. They were patients in hospital suffering from chronic illnesses that were unlikely to interfere with the reactions to the drug. An injection of 0.5 mg will produce definite effects, which, however, are sometimes so pronounced as to be upsetting to the patient, a dose of 0.25 mg will usually produce some recognizable effects, does not upset the patient, but seldom produces all the typical reactions.

Fig 5 shows the characteristic response to 0.5 mg. Within a few minutes, usually two, the subject becomes

Fig 5

restless, feels hot, flushes on the face, neck, and upper thorax, and swallows because of increased salivation and a vague feeling of constriction in the throat, and tears collect in the conjunctival sac because of increased lacrimation. Throbbing in the head may be complained of early, but may not appear for ten or more minutes. With the onset of the symptoms the pulse rate rises and the blood pressures fall, but after a few minutes, usually five, the pulse rate also falls to below the initial rate. In five to ten minutes after the injection sweating appears all over the body, and in from ten to fifteen minutes borborygmi are audible, the patient is conscious of abdominal unrest, and there may be some nausea. After twenty minutes the symptoms subside, and the pulse rate and blood pressures gradually return to normal, usually regaining the initial levels at the end of forty minutes. The abdominal unrest may continue after the other symptoms have disappeared, and frequently the bed pan is called for at the end of thirty to forty minutes, when defaecation may occur, or, more often, the bladder only is emptied. This dose produced in one subject an alarmingly rapid fall of blood pressure and of pulse rate with a feeling of faintness and appearance of collapse. Atropine sulphate was accordingly injected intravenously, this being followed by a rapid disappearance of all the symptoms.

If the dose is raised to 1 mg the effects are increased in intensity and in different subjects one or other effect attains especial prominence. Fig. 6 shows the result in a patient with muscular dystrophy in whom the most striking effect was the intense pain which he located at the root of the penis. This pain persisted after he emptied his bladder and remained severe at the end of forty minutes when other symptoms had disappeared or become mild and he was given atropine which promptly relieved the pain. Following the injection of 1 mg in the same subject is in Fig. 5 the slowing of the pulse and the fall of blood pressure were so rapid that atropine was given at the end of six minutes but the most striking phenomenon was the flow of saliva which frothed at her mouth in a large ball of fine bubbles. On the other hand 1 mg in another patient caused little disturbance apart from the usual effects on pulse rate and blood pressure and when

effect was the production of local constrictions. These changes were observable for one hour following the injection. Two patients with colostomy were given 0.2 mg and 0.4 mg respectively by subcutaneous injection. Between ten and fifteen minutes later increased movements were observed in the exposed parts of the colon which pouted and were vigorously contracted and with drawn while much wind was passed. With the smaller dose no other effects were observed but with the larger dose there was sweating and abdominal discomfort and the activity of the exposed gut was much more vigorous. The gastric contents were examined following an alcohol test meal in five subjects. At the end of one hour 0.1 mg or 0.2 mg of carbaminoyl choline was injected subcutaneously. No increase of hydrochloric acid occurred and in three subjects it was diminished although histamine caused increased acidity in all of them and following the carbaminoyl choline injections it sometimes proved diffi-

FIG 6

combined with 1 mg of atropine sulphate the atropine prevented the effects on the cardiovascular system but not entirely the increased movements of the intestines. The effects in a man with essential hypertension were in no way unusual 1 mg producing enough retching and vomiting to necessitate an injection of atropine to relieve his distress while 0.25 mg produced mild effects only (Fig. 7). In a woman with exophthalmic goitre the effects of 1 mg on the cardiovascular system were comparatively mild the bladder was emptied six minutes after the injection and abdominal unrest persisted for some hours even after defaecation occurred at the end of forty minutes.

As a result of their observations on the action in animals Kreitmair (1932), Noll (1932) and Velten (1933) pressed the effects on the gastro intestinal tract. We studied the effects of 0.2 mg to 0.4 mg in three human subjects by subcutaneous injections watching the outlines of the stomach and intestine with the x-ray screen following a barium meal. Fifteen minutes after the injection the movements of the stomach, small intestine and colon all appeared to increase. The stomach emptied more rapidly than usual and conspicuous local constrictions appeared in the small intestines and colon while from time to time a constriction would move vigorously downwards for a short distance. The normal movements seemed to be increased in vigour and frequency but the most striking

FIG 7

cult to obtain further specimens possibly because the stomach emptied rapidly.

Starr (1937) reported the effects on twenty six healthy students of giving 0.1 to 1 mg by subcutaneous injection and 0.4 to 1 mg by the mouth. He obtained a fall of blood pressure and a rise of pulse rate followed by a fall and noted symptoms similar to those found by us. He considered that it is cumulative both by mouth and by subcutaneous injection and that if repeated injections are given the dose must be reduced or headache and general malaise result.

Rutenbeck (1935) in a study of ionization as a method of introducing drugs into the body found that with a solution of 1 mg per ccm of carbaminoyl choline general effects were obtained from the absorption of the drug. He obtained local vasodilatation that was not so strong as with his amine and five to ten minutes after the circuit was closed flushing in the head, sweating, abdominal unrest and increased intestinal peristalsis were experienced. Kramer (1937) also obtained general effects of carbaminoyl choline by the same method.

Velhagen (1933) observed local effects in the eye following the instillation of a 0.75 per cent solution into the conjunctival sac. He found that it produced a strong constriction of the pupil and that it lowered the tension

in the eyeball if given two or three times a day With Dr Kent Harrison I have tried the effect when given in this way The ordinary solution for injection (doryl), which contains 0.25 mg per c cm, has no effect even when combined with 0.05 per cent solution of prostigmin, but we found that a 0.75 per cent solution as used by Velhagen produced a strong constriction of the pupil in two subjects that persisted for six hours, and also engorgement of the conjunctival vessels that passed off somewhat more quickly In five other subjects we put one drop of a 0.75 per cent solution with one drop of a 1 per cent solution of prostigmin into the conjunctival sac and obtained congestion of the conjunctival vessels and constriction of the pupil that persisted for eighteen hours in all of them, and in four a lowering of the intra-ocular tension could be detected with the finger-tips This lowering of eyeball tension is presumably due to the relaxation of the unstriated muscle fibres of the orbit, and was especially noticeable in a subject with exophthalmic goitre In no instance could we detect any dilatation of retinal arteries or symptoms of absorption of the choline ester into the general circulation

These results of the administration of carbaminoyl-choline to man show that it has in general the same actions as acetylcholine, but because of its increased stability it is effective by intramuscular and subcutaneous injection, and these actions can be maintained for a much longer time than is possible with acetylcholine By oral administration its effects appear to be less certain, and when given repeatedly malaise and headache result It can be administered slowly over long periods by ionization, and local effects in the eye can be obtained by conjunctival instillation Further, in comparison with acetylcholine the effects on the gastro-intestinal tract and the bladder appear to be greater and those on the cardiovascular system to be less The rise of pulse rate when a fall might be expected is probably due to a reflex action from the carotid sinus, resulting from the fall of blood pressure, overpowering the direct vagomimetic inhibiting action on the heart as suggested by Dautrebande (1933)

### Pharmacology of Acetyl- $\beta$ -methyl-choline

In 1911 Reid Hunt and Taveau reported the production of an ester of methyl-choline, acetyl- $\beta$ -methyl-choline, with well-marked parasympathetic and muscarine-like actions as of acetylcholine but feeble nicotine-like effects They found that it was less readily hydrolysed than acetylcholine Simonart (1932) confirmed these properties and actions in cats, and found that it was absorbed and active when administered by the gastro-intestinal tract Comroe and Starr (1933), working with frogs, cats, rabbits, and dogs, found that it has actions similar to those of acetylcholine, less powerful though more prolonged on intravenous injection, and that it is more effective on subcutaneous injection, and active when injected into the lumen of the intestine In the fully atropinized animal they obtained no rise of blood pressure, pointing to the absence of nicotine like effects on sympathetic ganglia or adrenal medulla, and the only nicotine-like effects obtained by Simonart were feeble ones on denervated muscle Schnedorf and Ivy (1937) found that in eight rhesus monkeys, with histamine-resistant achlorhydria but otherwise healthy acetyl- $\beta$  methyl choline alone by repeated injections caused a flow of acid gastric juice in half of the animals and that all responded when it was combined with histamine Flewener Bruger, and Wright (1938) showed that it caused contraction of the gall bladder in cats

### Action of Acetyl- $\beta$ -methyl-choline in Man

Acetyl- $\beta$ -methyl choline is usually administered to man as the chloride, which is supplied by Merck under the name of mecholol or mecholyl Villaret, Justin-Besançon, Cachera, and Said (1932) gave 25 mg by subcutaneous injection to healthy subjects, and found a fall in blood pressure that lasted for one or two hours, accompanied by vasodilatation and symptoms of vagus stimulation Villaret, Justin-Besançon, Schiff-Wertheimer, and Gallois (1932) applied it to the eye by instillation of two drops of a 10 per cent solution into the conjunctival sac and produced powerful miosis and a reduction of ocular tension They found that it had a powerful effect by subconjunctival injection also Starr, Elsom, and Reisinger (1933) gave it by subcutaneous injection to normal subjects in doses up to 25 mg, and observed flushing, a feeling of heat, sweating, salivation, lacrimation, increased intestinal peristalsis, epigastric discomfort, increased respiratory excursion, palpitations, and a sense of discomfort in the epigastrium and of constriction under the sternum The effects appeared in two to three minutes and passed off in twenty to thirty minutes The pulse rate rose and the blood pressure fell with the onset of symptoms, and a few minutes later the pulse rate fell in some cases to below the original level, an action similar to that of carbaminoyl choline by the same route They gave it by the mouth also in doses of 100 mg to 1 gramme, and found that when administered by this route the effects were much the same but less intense, persisted longer, and appeared in thirty to forty minutes When given orally the rise in pulse rate was not seen

Fig 8 shows the action of 25 mg by intramuscular injection in one of our patients The symptoms of

FIG 8

collapse and the fall of blood pressure appeared so rapidly that 12 mg of atropine sulphate was given by subcutaneous injection at the end of eight minutes In a second subject 12 mg of atropine sulphate was given twenty-four minutes previously and was not sufficient to prevent the cardiovascular effects of 50 mg

Abbott (1933) studied especially the actions on the gastro-intestinal tract When given by subcutaneous injection or by the mouth it caused increased movements

of the stomach, small intestine, and colon, and after oral administration the cardiovascular effects were less intense. He obtained no increase in the amount of gastric juice, but in a few cases of hypochlorhydria there was a slight rise in the concentration of free hydrochloric acid.

Pape (1935) observed the usual muscarine-like effects following the subcutaneous injection of 25 mg, but commented on the absence of slowing of the pulse. He found that the T waves of the electrocardiogram become negative following the injection, and that this effect in common with the other symptoms is inhibited by atropine.

Ritvo (1936) observed the effects of 20 to 30 mg of subcutaneous injection on the stomach and intestine by radiographs following a barium meal. He found an increase of tone in stomach and intestines five to ten minutes after the injection, followed by powerful deep peristaltic waves. In the colon the lumen narrowed and contractions increased in number and depth. These effects lasted for thirty minutes to several hours and were accompanied by evidence of parasympathetic stimulation and by headache, sweating, and a fall in blood pressure.

Myerson, Schube, and Ritvo (1937) observed the effects on the colon following a barium enema. They gave 50 mg by subcutaneous injection and found increased tone in five minutes, followed by more and more marked contractions coming and going for over one hour. The increased tone lasted sometimes for twenty-four hours, and as a rule three or four evacuations occurred. They found that the cardiovascular effects were of short duration, in contrast but considered that they were disadvantageous to the use of the drug in atony of the colon. Atropine sulphate in doses of 1/100 grain by subcutaneous injection inhibited these actions on the colon.

Myerson, Loman, and Dameshek (1937) found that following the subcutaneous injection of 30 mg the spinal fluid pressure rose by 30 to 140 mm of water during the lowering of the blood pressure in eighteen psychotic patients.

Myerson, Rinkel, and Dameshek (1936) studied the effect on the gastric juice following the subcutaneous injection of 25 to 40 mg. They concluded that it produces an increased flow of alkaline juice with a high mucous content and that free hydrochloric acid and total acidity are reduced. These effects began to pass off after twenty minutes and had disappeared by forty minutes. Loman, Rinkel, and Myerson (1937) found the same action on the gastric juice when the drug was given by ionization, but the effect was less explosive and the side effects less pronounced by giving prostigmin in addition. They were able to maintain an alkaline juice for two hours or more.

Martin (1937) obtained all the usual actions following absorption by means of ionization using a 0.25 or 0.5 per cent solution with a current of 20 to 30 milliamperes for twenty minutes. He observed that the blood sugar fell, but not convincingly, and that there was an increase of gastric juice with a fall in acidity. No case of anacidity developed free acid.

Van Dellen, Bruger, and Wright (1937) put 25 to 50 mg in a few drops of solution into the anterior nares. Evidence of immediate absorption was seen—hyperaemia and a sensation of warmth in the nose, lacrimation, salivation, flushing of head, neck, and thorax, sweating, and a sharp fall of blood pressure. The symptoms varied greatly from individual to individual and at times the respirations were accelerated; the effects passed off in four to six minutes.

Myerson and Thau (1937) found the effective dose when given by instillation into the conjunctival sac to be inconstant. A 10 per cent to 20 per cent solution usually sufficed to produce a pin-point pupil in twenty minutes. The reaction to light and convergence was retained until miosis was extreme; the palpebral fissures were narrowed, the retinal arteries and veins dilated, and the ocular tension fell 3 to 4 mm. A full effect could be obtained with a 1 per cent solution containing 1 per cent prostigmin. General symptoms of absorption did not occur.

From these observations we can conclude that like carbaminoyl choline, acetyl-methyl choline has actions similar to those of a muscarine and is more stable, producing a prolonged action even by subcutaneous or intramuscular injection or by the mouth or by ionization. By injection a dose of 10 to 20 mg appears to be comparable to 0.25 to 0.5 mg of carbaminoyl choline. The effects of both are ordinarily of the muscarine type, but the only remarkable effects observed by us were seen with carbaminoyl choline in muscle twitchings and clamping in a patient with muscular dystrophy and in increased spasm of muscles in a case of arteriosclerosis of the cerebral vessels. With both esters the results following injection appear in a few minutes, but while the action on the cardiovascular system passes off in from thirty to forty minutes, the action on the gastrointestinal tract and bladder may persist for several hours. It is generally accepted that the action of carbaminoyl choline on the gastrointestinal tract is relatively greater than on the cardiovascular system, and that the reverse is the case with acetyl-methyl choline. With both local effects can be obtained on the eye and on the nose by instillation into the conjunctival sac or anterior nares.

### Therapeutic Uses of Doryl and Mecholin

Both carbaminoyl choline chloride (doryl) and acetyl-methyl choline chloride (mecholin or mecholyl) have been used in a great variety of diseases to obtain either parasympathetic or vasodilator effects, but the reports in the literature of such uses have with certain exceptions consisted of a few case reports from which it is often difficult to judge conclusively of the value of these substances.

*In Ophthalmology*—Miloro (1935) considers that in chronic glaucoma the instillation of doryl is often efficacious when physostigmin and pilocarpine fail. He found that it produced a powerful miosis for two and a half hours and that the ocular pressure was lowered for twenty-four hours.

*In Ozaena*—Guns (1934) believes that doryl has a place in the treatment of ozaena and found that the local application of a 0.04 or 0.05 per cent solution caused increased secretion.

*Contraindicated in Asthma*—Starr, Elsom, and Reisinger (1933) caused an attack of asthma by mecholin in an apparently healthy person who had been subject to asthma, and Villaret, Vallery Radot, Justin Besançon, and Claude (1934) reported that in fifteen persons subject to asthma with various causal factors attacks were produced by the subcutaneous injection of 0.02 to 0.04 gramme. They suggested that this effect might be used as a diagnostic test. My colleague Dr J. G. Scadding has demonstrated by means of lipiodol constriction of the smaller bronchi following 25 mg of mecholin by intramuscular injection in a woman aged 37 convalescent from pneumonia and with no history of asthma.

## HEREDITARY BONE TUMOURS IN MICE

BY

F. C. PYBUS, M.S., F.R.C.S.

AND

E. W. MILLER, B.Sc., Ph.D.

(From the J. H. Burn Laboratory, Royal Victoria Infirmary, Newcastle upon Tyne)

(WITH SPECIAL PLATE)

It should no longer be disputed that a tendency to cancer is often inherited. While there is ever-accumulating evidence to show that this is so in man, of which probably every practitioner must have seen examples, most of the experimental proof has been obtained by animal breeding. The inheritance of mammary cancer in mice is being very

fully investigated, chiefly by American workers. Certain strains which have been inbred for many generations are characterized by a definite and constant cancer incidence, high in some strains, in intermediate or low in others. Once these characters are established such strains are used extensively for investigating the origin of mammary carcinoma. Other inbred strains have proved the inheritance of a leukaemic tendency while in others there is a regular production of tumours of the liver or lung.

In 1929 a pair of mice from the Simpson strain (developed by Dr. Burton J. Simpson of Buffalo from the Lathrop-Loeb stock) was given to us by Dr. T. Lumsden. From this pair we have bred more than 5,000 descendants. The general incidence of mammary carcinoma is over 50 per cent (in some inbred lines it is considerably higher). Lung tumours are very frequent, and other lines have a high incidence of leukaemia. Angiomas, epitheliomas, and other neoplasms are less numerous.

## Sarcomata

Sarcomata were known to occur but rarely in the strain. The first six cases in our stock appeared in 1933, three of these being of bone and three subcutaneous. Mouse 100, the first to produce a bone tumour, had a sarcoma of the sternum in addition to a mammary carcinoma. The relations and descendants of these sarcoma mice were

bred from, certain lines were inbred brother to sister, others were outcrossed in an attempt to increase the sarcoma incidence. During the next two years there were forty-two cases of bone tumours, mainly sarcomata, in this group. One of these, a female of 5½ months, had a hind limb amputated for a sarcoma of the tibia and was paired to a sarcoma-bearing male. The descendants from this mating, together with those from three other double sarcoma pairings, formed the nucleus of our present inbred sarcoma strain, now in its seventh generation. The sarcoma incidence in one line is shown in Fig. A.

The sarcoma incidence in the ordinary Simpson stock is approximately 1 per cent. During the first four generations of inbreeding it increased to 10 per cent. In our inbred strain from the double sarcoma pairings it is just over 50 per cent. At the time of writing there have been ninety-six cases of bone tumours in the inbred strain.

among 188 mice which have died over the age of 5½ months. There is a curious difference in incidence in the sexes, the females producing three times as many sarcomata as the males.

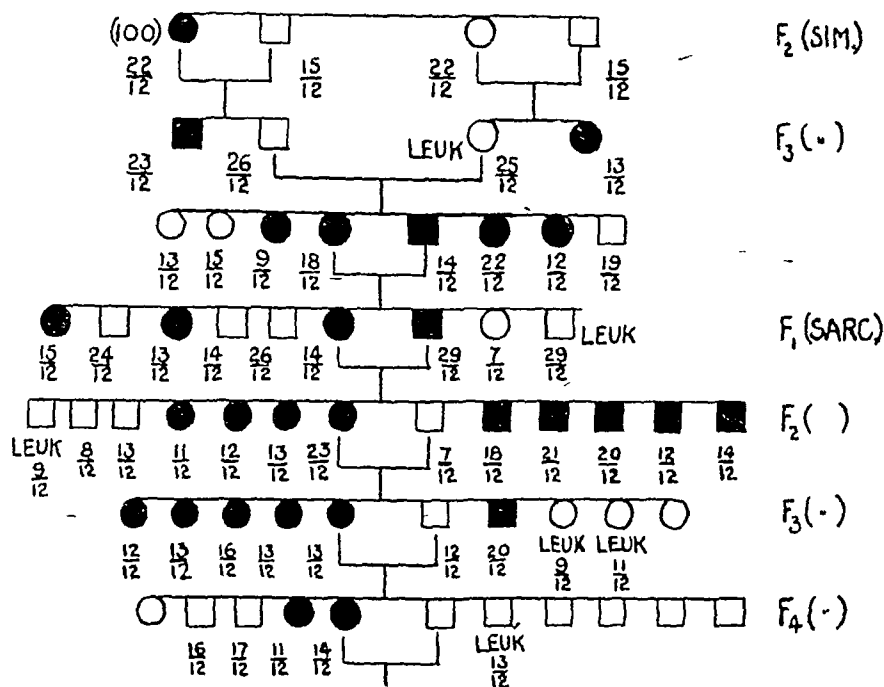

FIG. A—The pedigree of one line of the sarcoma strain showing the high incidence of sarcoma. The age of the mouse at death or appearance of the tumour is given in months. Where no age is given the mouse is still living.

○ = female, ● = sarcoma-bearing female, □ = male, ■ = sarcoma-bearing male, LEUK = leukaemia, SIM = Simpson stock.

usually the first indication of a vertebral tumour. Large tumours about the pelvis may impede locomotion or parturition while in others intracranial growths may be suspected. Diagnosis has been confirmed in some cases by

FIG. B—Right femur and tibia from mouse 3754, o.c. (o.c. = osteogenic sarcoma of femur, slight changes in tibia).

X-rays, which are a ready means of revealing multiple lesions or metastases (Plate Fig. 1). An analysis of the sites shows that any bone may be affected (in one mouse the whole skeleton was altered), but the more common

sites are the femur, tibia and spine, and occasional tumours of the jaw, skull, humerus, ribs or sternum are met with.

The main types recognized are osteomata composed either of compact or of cancellous bone alone or in varying proportions and in some cases associated with chondrification or rapidly growing soft tissue. The cancellous osteoma local or diffuse is the most common type.

### Histology

Histological examination demonstrates all stages in the development of bone tumours. The earliest phase consists of proliferation of the osteoblasts forming local hard or cancellous tumours (Plate Fig. 2) single or widely distributed throughout the skeleton. This change may be confined to a small area, but more often it increases in extent until most of the bone is affected. At any time this proliferation may pass beyond the limits of the periosteum and invade the surrounding tissues. Again at any point proliferation may show giant-celled tissue or may pass into a purely spindle-celled rapidly growing sarcoma (Plate Fig. 3). Metastases are found in the lungs, liver, kidneys and spleen. Like the parent tumour they show all grades of bone formation.

The essential feature of the tumours seems to be a varying degree of neoplasia of the osteoblast. In their varying degrees of differentiation and malignancy they show an exact analogy with the mammary tumours which range from a single adenoma through all the stages to a generalized carcinoma of the whole mammary tissue.

### Conclusion

With the possession of this inbred sarcoma strain which reproduces many of the bone lesions known in human pathology it may be possible to investigate the proximate cause of bone tumour formation and perhaps solve other problems concerning bone neoplasia.

Research into this subject and the investigation of rarer types of bone pathology are proceeding.

This work was carried out under a grant from the British Empire Cancer Campaign.

C. Coggi (*Ann. Ostet. Ginec.* February 28 1938 p. 107) discusses the aetiology, morbid anatomy, symptomatology and treatment of necrobiosis of uterine fibromyomata during pregnancy. Six personal cases he describes include three cases of total aseptic necrosis and one case each of partial aseptic necrosis, red degeneration and aseptic necrosis. As a result of his investigations he comes to the following conclusions: (1) Aseptic necrosis in uterine fibromyomata during pregnancy is fairly infrequent and is chiefly found in primiparae of a relatively advanced age; the immediate cause is ischaemia. (2) The symptoms consist chiefly of pain in the hypogastrium accompanied by tenderness on pressure over one particular spot and general disturbance which may range from slight pyrexia to cachexia and even acute peritonitis. (3) Expectant treatment is dangerous and unreliable and should only be adopted in special cases. (4) Myomectomy is the treatment of choice whenever possible; the fear of myomectomy being followed by abortion should not prevent the performance of this operation since the patient will be in a better state to face another pregnancy. (5) The prognosis is always grave and whatever be the treatment adopted necrobiosis is dangerous for the mother and in most cases fatal to the foetus.

## A CASE OF ABDOMINAL PREGNANCY

RONALD REID, M.S., F.R.C.S.

1, 101 St. Vincent Street, Glasgow, Glasgow Hospital, Glasgow

(WITH SPECIAL PLATE)

Although many cases of abdominal extra-uterine gestation have been reported in recent years the condition is one of the most difficult to diagnose. The diagnosis is difficult because of the many causes which may give rise to it. In this case the condition was found at the time of a laparotomy which had been made in only 35 per cent of the cases reported. Before proceeding to report the case the following remarks will be relevant. Firstly, it is to be noted that the knowledge of this condition for many years has been related to the exhaustive study of the condition in the animal body.

### Present knowledge of the Condition

Abdominal pregnancy has been reported in women whose ages range from 15 to 64 years, the 64-year-old patient having carried her foetus forty years. Under 2 per cent had previously lived ectopic pregnancy and the condition has seldom complicated other diseases or tumours. The chief symptoms are abdominal pain and this is often associated with slight vaginal haemorrhage and attacks of fainting or vomiting. On abdominal palpation the foetus may be felt separate from a moderately enlarged uterus and lying higher than the normal foetus. The cervix, though so it is less so than in a case of normal pregnancy and it is often high up behind the symphysis pubis. Exploration of the uterine cavity with a sound or hystero-graphy after iodol injection has been found of considerable diagnostic value.

Deformities are the rule in the baby; these are often due to pressure only eight cases out of 236 having been reported as normal. The foetal mortality is high in eighty-six cases in which the baby was born after six months the mortality was 22 per cent, whereas in sixty cases in which the baby was born alive in the eighth and ninth months the mortality was 35 per cent.

The maternal mortality was 14 per cent in the 236 cases; shock, haemorrhage and peritonitis accounting for the majority of deaths. It has been taught that in abdominal pregnancy operation may be probably delayed until the foetus is dead and the placenta thrombosed and relatively avascular, but Cornhill and Lash have shown that in the cases so treated the maternal mortality was 33 per cent, thus forcing one to the conclusion that such a teaching is erroneous. These authors also point out that operative treatment should include the removal of foetus, membranes and placenta *in toto* as the mortality of such a procedure—being 10 per cent—compares very favourably with a mortality of 20 per cent in cases treated by leaving the placenta with or without marsupialization. However it may be that the high mortality of the latter policy may be partially accounted for by its being adopted in the more advanced cases or with more serious ill patients. Certain other writers on the other hand consider non-interference with the placenta to be the wisest course and report its complete absorption in a few months.

Upon the question of the optimum time to operate for the safety of the mother and child the conclusion is that as the policy of delay has been shown to be fraught with

greater risk—since placental separation and rupture of the sac are ever-present dangers—operation is indicated as soon as the diagnosis is made. The delay necessary to obtain a living child is never justified in the face of the danger to the mother, the high foetal mortality, and the incidence of deformities.

### Case History

The patient a housewife aged 31, was admitted to the cottage hospital on October 28, 1937. She had two children, aged 2 and 5 years. She was small and plump, but looked pale and ill. Her last period was on August 12, and was quite normal. On October 13 the patient noticed a small vaginal show which cleared up in a few days, and she remained well until about six days before admission, when there was pain in the lower abdomen, nausea, and a slight rise in temperature. The pain cleared, but the abdomen was still uncomfortable, and in the early morning, two days before admission the patient went downstairs and collapsed on the floor where her husband found her. Her doctor states that the pulse was thin and rapid and the skin cold, he moved her to hospital, where she rapidly recovered. When examined two days after admission she was pale, and was in considerable pain. The pulse was 90 and the temperature  $101^{\circ}$ . The abdomen was tumid and resistant below the umbilicus, but not rigid. There was a profuse thick yellow vaginal discharge, with marked tenderness on rectal examination, but no mass was palpable. On vaginal examination the cervix was soft but the uterus could not be defined.

Two weeks later the patient was seen again, and her general condition was found to be much improved, the pulse was normal and the temperature varied up to  $100.8^{\circ}$ , but she still had occasional abdominal pain, notably after an enema had been given. On examination there was some resistance, but the uterus could be felt to be about the size of an orange, and in the pouch of Douglas was a soft ill defined mass. A conservative policy was advised with regard to the mass, and local heat was applied as fomentations and douches.

On my next visit to the cottage hospital the patient had been discharged but she was readmitted on January 15, 1938, because it had been noticed that the abdomen was increasing in size in a manner not associated with the swelling of normal pregnancy. The enlargement was mainly to the left of the mid line. On examination there was no increase of pulse or temperature, the general condition of the patient was good but the abdomen showed two separate swellings. The uterus the size of a four-months pregnancy was situated to the right side of the hypogastrium, while to the left was a much larger tumour, ovoid in shape, extending in a curved manner to a height above the umbilicus and to the left of it. The mass was soft movable of even consistency—not tender—and its lower pole of identical fluctuant softness, could be felt in the pouch of Douglas. The biological test for pregnancy was positive.

Although it was noted that the uterus was small for the estimated duration of pregnancy, the diagnosis of abdominal pregnancy was not considered, and the case was labelled one of pregnancy complicated by an ovarian cyst with the observation that perhaps the original pain had been due to partial rotation of a cyst which was at that time smaller and concealed by the resistant abdominal muscles. In view of the rapid increase in size of the tumour operation at an early date was advised and the patient kept in hospital. A few days later an enema given in the course of routine preparation for an operation, precipitated an attack of violent general abdominal pain. The patient was anxious, the respirations short and the pulse rate raised. The abdomen previously soft enough to allow of easy examination became tense rigid, and exquisitely tender.

Under gas oxygen ether anaesthesia the patient was submitted to laparotomy. By a right paramedian incision the peritoneum was opened to allow of the immediate outflow of dark fluid blood. This was cleared away and on retracting the edges of the wound a large ovoid, smooth, dark blue,

glistening tumour was seen lying in the left side from the pelvis upwards. Within could be seen foetal parts floating in an excess of apparently clear amniotic fluid. As blood welled freely up from the pelvis haste was made to deliver the whole foetus together with its sac which was scarcely adherent to surrounding structures. The cord was cut, the intestines drawn to one side, and the placental site examined. The placenta was a large disk, well formed and covering the right broad ligament, the right side of the enlarged and soft uterus, and the lower pole of the caecum. Blood issued rapidly from beneath its detached edge, and so it was quickly peeled off and the haemorrhage controlled by firm pressure applied with hot packs for five minutes without ceasing. On then examining the site the haemorrhage was seen to have diminished and the ovarian vessels and an extended upper branch of the right uterine artery were ligatured. The roughened broad ligament was thereupon doubled over and sewn down, raw surface to raw surface. The haemorrhage was not difficult to control and the abdomen was closed. Half a litre of glucose saline was given intravenously by the drip method, and 1/3 grain of morphine was injected hypodermically. In four hours the patient had a pulse of 120, and from then onwards she made a steady recovery.

### Description of the Foetus

The foetus (see Plate) weighed about sixteen ounces, and its total length from vertex to heels was about eleven inches. The skin was wrinkled, firm, and reddish in colour, and there was some sebaceous material about the groins. The legs were slightly longer than the arms. The back was bent forwards in a sharp dorsal kyphosis and the head was flattened from side to side, and was of a peculiar scaphoid shape as if it had been moulded round a prominence. The mouth, eyes, and ears were fairly well formed.

On delivery from the mother's abdomen the foetus was alive and moved quite vigorously, at the same time making many gasping attempts to breathe. After five minutes all trace of life had passed.

### Commentary

It will have been noticed that this case conforms with those reported in that the mother was a previously normal woman who, on becoming pregnant, had a show of blood after a month and then severe abdominal pain, also that she carried her ectopic foetus unsuspected until eventually she was delivered of a premature and deformed child by abdominal section.

The possibility is that pregnancy started in a Fallopian tube, there was a warning haemorrhage a month later, and at the sixth week a tubal abortion occurred. The embryo must then have found new and satisfactory attachment or retained sufficient of its old connexions to survive and grow. The later attacks of pain must have been recurrent haemorrhages culminating in a loss causing symptoms and signs which demanded laparotomy. Despite the fearsome vascular bed promoted at the placental site by the action of the growing embryo, control of the haemorrhage after delivery of the foetus sac, and placenta was not difficult, and was mainly effected by the pressure of hot packs for five minutes without relaxation.

## KERATOPLASTY WITH REPORT OF A CASE

BY

T. H. S. TIZZARD, M.B., Ch.B., D.O.M.S.

*Honorary Surgeon, Eye Infirmary, Bath*

(WITH SPECIAL PLATE)

During the last few years isolated accounts of successful corneal grafting by surgeons in this country and particularly on the Continent have appeared in ophthalmological and medical journals and the various methods employed by ophthalmic surgeons have been fully reported. Elaborate methods of corneal grafting might well deter many oculists from attempting to perform the operation. In this paper it is intended to describe the simple technique employed with complete success in a case towards the close of last year.

Much experimental work has been done during the past thirty years with varying degrees of success. The degrees of success as described by various authors may be grouped under three headings: (1) clinically transparent; (2) slight degree of opacity in the graft or behind the graft resulting from the formation of a fibrous tissue membrane; (3) much opacity but less than originally. The visual acuity will depend not only upon the transparency of the transplant, but also upon the transparency of the lens and vitreous and the condition of the retina.

There are three methods of keratoplasty: (1) total; (2) partial superficial; (3) partial penetrating. In the two former methods the transplant becomes opaque in a period varying from three weeks to a few months. The last method offers the best permanent results. If the graft remains transparent for a period of one year the result is said to be permanent. I quote this from Elschnig's and Filatov's observations. The transplant must be taken from the same individual (autoplasty) or from individuals of the same species (homoplasty). Hetero transplants invariably become opaque. The homogeneity of the donor's and the recipient's blood grouping appears to be of no importance.

### Case Record

Eighteen months previously the patient, a young woman aged 23, had a severe interstitial keratitis of both eyes resulting in opacities of both corneae. The Wassermann reaction was strongly positive. She received vigorous treatment for the condition at the Bath Eye Infirmary for five months. Mercury and iodide were given and she received three courses of chemical treatment. A year after the beginning of treatment the eyes became white. In November 1937 right vision was +60 and left vision was limited to hand movements. As vision in the left eye was the worse I decided to operate on this eye. A donor was found—a patient who was being treated for a perforating injury to the sclera which resulted in loss of vitreous and complete detachment of the retina. The wound was stitched but the eye remained irritable and so enucleation was indicated.

### PRE-OPERATIVE PREPARATION

The blood group of the donor was A and that of the recipient B. Cultures were taken from the conjunctival sacs of the donor and the recipient. No pathogenic micro-organisms were grown during forty-eight hours incubation. For some weeks previously the sacs of the recipient had been irrigated with 1000 hydrarg. oxycyanid 1 in 10000 three times a day. An apertent was given the evening before the operation and a drop of eserine 1 per cent aqueous solution

was instilled into the left eye. On the day of the operation the left conjunctival sac was irrigated with normal saline and the lids were everted. The skin of the lids and the area in the conjunctiva were painted with a solution of brilliant green in spirit and a drop of eserine was again instilled into the left eye.

### OPERATION

The recipient eye was anaesthetized with several drops of cocaine 4 per cent. Four or five drops of adrenaline 1 in 1000 were instilled at intervals of a few minutes. A facial nerve block with 2 ccm of 2 per cent novocain injected at the point where the upper branch of the ophthalmic cranial nerve crossed the neck of the condyle of the mandible, each within 1 cm of the ocular globe and lid speculum was tied during the anaesthesia. A No. 1 Hudson's wire the conjunctiva was incised round the limbus in the upper half from 12 to 9 o'clock and under tension of 10 or so that it could be drawn down over the entire cornea at the conclusion of the operation and sutured to the sclera. Three sutures of No. 1 black silk were passed from the conjunctiva near the cut edges (see Fig. A). The site of the graft is delineated

FIG. A.—Diagram showing position of sutures (S) which are tied below after the graft is in position.

by placing No. 1 trephine (4.65 mm) over the centre of the cornea and cutting through the epithelium. The trephine was removed and a drop of sterile fluorescein was placed on the cornea. This outlined the graft. The trephine was again applied and when a section had involved half the thickness of the cornea the trephine was slightly tilted to one side so that the cutting edge was directed obliquely through the deeper layers of the cornea. The anterior chamber was thus entered. The trephine was removed and the action completed by dividing the remainder of the cornea with a pair of scissors whose cutting edges were bevelled.

The eye of the donor was enucleated and immediately immersed in a watery solution of brilliant green 1 in 2000 and then transferred into physiological saline at body temperature. The eye was held in the left hand and the graft removed in the same way as from the recipient's eye but using a 4.65 mm trephine. By using a trephine a little less in diameter the piece of cornea could easily be fitted into the bed prepared. The graft was removed by sliding a repositor beneath it and it was then placed in a watch glass filled with sterile normal saline at about blood temperature. The bed of the graft having been prepared the graft was lifted on to the upper surface of a spatula transferred to the corneal bed and fitted as accurately as possible so that the surface of the graft was flush with that of the surrounding cornea. The corneal flap was drawn gently over the entire cornea and the sutures tied. Sterile atropine oil 1 per cent was instilled and both eyes were firmly bandaged. Luminal 1 grain was given twice daily.

### POST-OPERATIVE COURSE

On the second day the patient complained of severe pain in the operated eye. The bandages were removed and one drop of oily atropine was instilled into that eye. Both eyes were bandaged again. Hereafter the eye was dressed every day and atropine was instilled. On the fourth day the conjunctiva had receded from the cornea exposing the graft which was

transparent Ten days after the operation the right eye was uncovered The graft acting as a foreign body, caused great irritation and in consequence a white fibrous ring began to form round it A number of small blood vessels could be seen growing superficially in the cornea from the limbus towards the transplant As time went on these vessels encroached upon the margin of the transplant, but never at any time did they grow to the centre By the third week from the date of the operation the eye became quiet and the bandages were removed Six weeks after the operation vision with correction was 6/36 This rapidly improved Now, six months after operation, the graft is quite transparent, the pupil is freely active, and there are no anterior or posterior synechiae The fundus can be clearly and distinctly seen with the ophthalmoscope, and the field of vision is fairly full Vision with correction is 6/5 partly and the patient can read the smallest print She is now able to take an interest in life, and can follow her former occupation of a shop assistant (The two figures in the Plate show the condition of the eye before and after operation)

This is believed to be the best visual result so far reported in this or any other country, vision having been completely restored

### Comments

1 The operative procedure in this case is simple, and requires no elaborate instruments

2 With a larger trephine than the one used, anterior synechia would be more likely to occur, resulting in opacification of the graft With a smaller trephine than 4 mm the fibrous tissue ring which forms at the junction of the cornea and transplant is apt to occlude the small central clear area of the graft

3 By contracting the pupil with eserine before trephining the recipient's cornea there is less likelihood of injuring the lens when preparing the bed for the transplant

4 To bring the conjunctiva over the cornea in the manner described is better than dissecting the conjunctiva from the whole limbus and drawing it over the cornea by a purse-string suture, as by this latter method the graft is more easily dislodged from its bed

5 The graft should be very carefully trephined, as Descemet's membrane easily buckles and detaches at the cut edge

6 Local anaesthesia is preferable to general anaesthesia as it eliminates post-operative unrest

This case was shown at a meeting of the Brith Clinical Society last February

My thanks are due to Dr H J Heathcote for examining the blood for the Wassermann reaction and for the blood-grouping in the two cases

According to official reports the year 1937 in Czechoslovakia was characterized by an almost general rise in infectious diseases Typhoid fever was very frequent in the eastern provinces diphtheria showed considerable recrudescence in Bohemia there was a rise in malaria and influenza caused almost twice as many deaths as in 1936 On the other hand the decline in tuberculosis continued and scarlet fever measles, and whooping cough claimed fewer victims

## SUPERIOR PULMONARY SULCUS TUMOUR

BY

J L RYCE, B M, B Ch.

Borough Hospital, Southampton

(WITH SPECIAL PLATE)

The condition described by Pancoast in America in 1924, and called by him a superior pulmonary sulcus tumour, gives a definite clinical syndrome and is rare enough to deserve mention Comparatively few cases have been reported, and these mostly in America

The patients are of the carcinoma age, usually male, and present themselves on account of pain in the region of the shoulder, shooting down the inner side of the arm and forearm The pain is more or less constant, is very intractable, and persists during the course of the illness, which is usually less than a year Loss of power and wasting in the muscles of the hand follows, and is associated with Horner's syndrome (paralysis of cervical sympathetic) of the same side (contracted pupil, enophthalmos, and lack of sweating with dryness of the face and neck) At the same time dullness at the apex of the lung may be made out, and as the disease progresses a hard indefinite mass may be palpated behind the clavicle Repeated radiographs will show a small circumscribed shadow at the apex of the lung and gradual destruction of the posterior parts of the first and, later, the second and third ribs, together with the adjacent articular and transverse processes and sides of the bodies of one or more vertebrae The apical shadow remains fairly circumscribed, with a lack of intrathoracic metastases All the cases are typical, Horner's syndrome being an essential feature The ulnar pain, the wasting of hand muscles, and the Horner's syndrome place the lesion in the region of the common trunks from the eighth cervical and first thoracic nerves as they issue from the intervertebral foramina

### Case Record

The present case was that of a man aged 50 years a butcher, who had been attending the medical outpatient department of the Royal South Hants and Southampton Hospital for some years with tabes dorsalis He was sent to us on July 8, 1937 with a tentative diagnosis of angina pectoris, as he had complained of pain in the left side of his chest and left arm for the past ten weeks This was worse on exercise and better on raising the arm above the head He had had a right hemiplegia twenty five years ago in which he lost his speech, but this had recovered considerably

On examination he was found to have considerable arterio sclerosis His blood pressure was 160/90 There was no great enlargement of the heart and no murmurs The right pupil was larger than the left, and both were inactive to light and accommodation No knee jerks were demonstrable but his right arm and leg showed weakness and loss of power, and he gave bilateral Babinski responses Marked hyperaesthesia of the left chest and shoulder was present The central nervous system was otherwise normal as were the other systems The Wassermann reaction was positive

An electrocardiogram taken on July 18 was normal On July 22 radiographs showed no evidence of aneurysm At this date the left apex was found to be dull to percussion but there was no cough or sputum X ray films taken on August 16 revealed no cervical rib but there was definite erosion of the tip of the first dorsal vertebra (? tuberculous or syphilitic) which appeared to be associated with a containing cyst At this time a lump could be felt behind the inner third of the left clavicle and he complained of pain and numbness

on the inner side of the left arm with weakness of the hand grip and fingers.

On September 5 definite wasting of the left palmar muscles and loss of hand grip were observed. He now received injections of NAB bismuth and sodium iodide. He was seen by Mr. Nightingale and Dr. Fisher who thought this to be definitely a case of new growth at the left apex (probably bronchial). On the 12th there was oedema and swelling of the left arm (due to lymphatic or venous obstruction) and left Horner's syndrome. Another radiograph taken on the 15th showed that the condition was worse; there was more erosion of the seventh cervical vertebra, the first rib had disappeared, and the second partly disappeared at the head and neck (Plate Fig. 1). From this time the patient went rapidly downhill, his temperature became elevated and he died on September 28.

**Post mortem Examination.**—A large mass was found at the left apex involving the lungs, upper three ribs and the vertebrae and surrounding the left subclavian vein which was thrombosed. No primary was present elsewhere but there was terminal pericarditis and pyaemic abscess of the kidney. The growth had the consistency of an unripe pear and had completely replaced the upper two ribs, which could be cut easily with the knife. Sections of lung, ribs and cervical glands were made.

**Report of Sections.**—All sections showed squamous celled carcinoma with cell nest formation (Plate Fig. 2). Catarrhal pneumonia was present in the lung.

#### Commentary

This case corresponds exactly to the description given by Pancoast and is actually more complete owing to our being able to obtain a full necropsy. None of the original cases apparently were examined post mortem. The result of microscopy does not settle the vexed question of the origin of the tumour which Pancoast suggested was in the remnants of the fifth branchial cleft. A tumour in this situation gives none of the common symptoms of carcinoma of the lung such as cough, sputum or haemoptysis. Its symptoms and signs are due entirely to pressure and mechanical involvement of the structures in its neighbourhood; consequently the picture may be given by any tumour which encroaches upon this particular situation. Cases described by Evans, Tobias, Steiner and Francis, Jacoby and others all exhibited the typical x-ray appearances and clinical features but were shown to be due to various tumours such as thymomas, sympathoblastomas, secondary growths from stomach and cervix uteri and breast and bronchial carcinoma. The last mentioned forms the largest proportion of the cases and probably is the usual cause of the syndrome. Browder and de Veer in describing another case suggested that the name of carcinoma of the pulmonary apex is more appropriate than that applied by Pancoast. Our case may therefore have been a squamous cell type of carcinoma at the apex, originating most probably in the lung but possibly in a branchial remnant.

The differential diagnosis includes several widely differing conditions. Cervical rib and syringomyelia may be excluded by the x-ray appearances. Tuberculous fibrosis at the apex does not cause destruction of the ribs or vertebrae. Endothelioma of the pleura spreads more rapidly and again there is no bone change. Osteogenic sarcoma of the ribs or spine in this region may contuse but there is generally widespread metastasis to other organs, the superior sulcus tumour being circumscribed and only spreading locally.

All the patients have been unrelieved of their symptoms by any procedure surgical or otherwise, and a feature of

the condition is its rapidly progressive and fatal course. The growth seems to be completely resistant to irradiation treatment which was given in the majority of cases reported. Jacoby suggests the frequent metastasis of bronchial carcinoma to the suprarenals as a cause of the rapid decline. Such metastasis however has not been demonstrated in any case.

I am indebted to Dr. M. K. Jardine for assistance with the case history and to Mr. H. J. Nightingale and Dr. D. Fisher for permission to report the case.

## FAILED SPLENECTOMY IN ACHOLURIC JAUNDICE, AND THE RELATION OF TOXAEMIA TO THE HAEMOLYTIC CRISES

BY

W. N. WEST-ATSON, M.D.,

L.D.S.

C. J. YOUNG, M.B., Ch.B.

(From the Bradford Royal Infirmary)

The accepted treatment for acholuric jaundice is splenectomy and in the majority of cases there is little doubt that the results are good. Cowen (1936) mentions the generally accepted view that the operation brings about complete and lasting freedom from symptoms. Dawson (1931) states: "Even in the severe anaemias the recovery is rapid and permanent and the patients are thenceforth healthy." Pemberton (1931) however summarizes the results in 118 cases operated upon between 1911 and 1931 in the Mayo Clinic. The hospital mortality was four subsequent deaths numbered eleven (six stated to be due to unrelated causes); eighty-two patients were alive and well and fair and poor results were obtained in sixteen cases. Difficulties exist in the interpretation of these figures but some degree of failure apparently resulted in at least 20 per cent. the true figure being probably higher. While the author believes that splenectomy should be advised as the safest form of treatment in all cases these figures suggest that the results may not be so good as some writers would indicate.

Examination of the literature shows that failure of varying degree has been due to operative mortality complications such as hepatic disease and other types of anaemia, and inability to achieve temporary or permanent relief from excessive haemolysis. Relief from the latter is the direct object of the operation and in this paper consideration is directed chiefly to this question. We have failed to find any published data of its frequency.

It has been recommended that to prevent possible future haemolytic crises splenectomy should be carried out even in slight cases especially if the family history is bad (Cowen 1936). Probably this is effective in many cases but it is clear from the literature (Freund 1932) that the operation does not guarantee freedom from such crises.

There appears to be some factor which converts latent into acute acholuric jaundice, and as many of these patients are quite well between haemolytic attacks, some information as to the cause of these latter is desirable. Consideration of some of the failed splenectomies, including one of our own, and various other cases, suggests that toxæmia may be one of the factors stimulating haemolysis.

### Failed Splenectomies

Freund (1932) quotes six cases from the literature, and records two others, in which operation failed to relieve the haemolysis permanently. Freund's first was a case of congenital acholuric jaundice in a boy aged 10 in whom haemolysis continued without remission after splenectomy, with pyrexia and abscesses, but necropsy gave no clue as to why the case differed from others in which splenectomy was successful. The second case was that of a girl of 11, with chronic bronchiectasis and hyperthyroidism, both of which preceded any history of jaundice. Considerable improvement followed splenectomy, but nine months later she developed a sore throat with pyrexia, and jaundice followed a few days later, death ensuing rapidly. Post-mortem examination showed bronchopneumonia with pus in the dilated bronchi. The author questions the advisability of splenectomy in this case, owing to a possible depression of the defence mechanism against infection. She also suggests that further studies should be made to ascertain whether or not chronic infection occurring in a case of haemolytic jaundice should be considered a contraindication to splenectomy. Both these cases showed increased red cell fragility.

A. C. and A. Van Ravenswaay (1934) recorded a case of haemolytic jaundice with normal red-cell fragility associated with an infection of the paranasal sinuses and the left ear and mastoid. Multiple transfusions failed to cure, and splenectomy was followed by only temporary improvement, but remission eventually occurred. Further attacks of sinusitis were associated with jaundice and anaemia, and in each instance improvement in the sinus condition was accompanied by an improvement in the anaemia.

Lovibond (1935) records a case in which, eight days after splenectomy, the patient died from a streptococcal infection. There was a history of a mastoid operation five years previously, following which she had been treated for anaemia. Liver, iron, blood transfusion, and splenectomy all failed to improve her condition. Increased fragility was found in one out of six tests. "The probable cause of the anaemia was thought to be either acholuric jaundice or an infective process."

### Relationship of Toxæmia to the Haemolysis

The question of the presence or absence of infection or toxæmia and its possible relation to the haemolysis is one of special difficulty.

Some authors accept the presence of pyrexia and leucocyte changes as evidence of infection, but the products of the rapid blood destruction might be sufficient to account for these phenomena (Joules and Masterman, 1935). Also, it is a common experience that cases of severe anaemia tend to be febrile whatever may be the actual mechanism involved (Lovibond 1935). While these points constitute no evidence against the toxicæmic theory, they render pyrexia and leucocythæmia inadequate for establishing its causal relation. Almost twice the clinical evidence of an association between infection and the decline in haemoglobin is available in two of the crises quoted and whooping fluctuations of each in one case being particu-

larly suggestive. Further examples of this relationship are provided by the following cases.

Dedichen (1937) records an epidemic of haemolytic crises in two families, eighteen members of which were found to have familial haemolytic jaundice. The author suggests that the acute manifestations were precipitated by what was presumably influenza. Scott (1935) records an epidemic of crises occurring at short intervals in four members of one family (increased fragility in all), suggesting an infection, although Scott does not favour this view. Infection, nevertheless, does not appear to be excluded, and the epidemic nature of the attacks is suggestive, and is not otherwise explained. It is doubtful, however, if the crises were entirely haemolytic in character. Estu and Lenci (1931) record a case which developed a haemolytic crisis with palpable spleen following the onset of a tonsillar infection. After tonsillectomy the red cell count rose almost to normal and the spleen became impalpable. Splenectomy was not performed.

Lederer's acute haemolytic anaemia bears a close resemblance to the crises of acquired acholuric jaundice, and Lederer (1925, 1930) in recording six cases of acute haemolytic anaemia suggested that they were due to infection, basing this opinion on the sudden onset and the presence of fever and leucocytosis. In discussing this condition O'Donoghue and Witts (1932) emphasize the slenderness of the evidence on which anaemia is attributed to foci of infection. They conclude that this acute haemolytic anaemia appears to be a specific illness due to infection, but the nature of the infection is unknown. In selecting thirty-six cases from the literature for consideration, however, they have rejected all with proved infection.

In the absence of experimental evidence the examples quoted do no more than suggest that toxæmia may be a possible factor in the haemolytic crises of acholuric jaundice. This possibility receives some support from the following case, in which splenectomy was performed during a haemolytic crisis without success, but after removal of an ovarian teratoma recovery ensued.

### Case of Failed Splenectomy

The patient was a married woman of 44, and was admitted to hospital with a two months history of shortness of breath on exertion, increasing pallor, and some loss of weight and appetite. She had had no menstrual period for five months. There was no history of previous jaundice and no family history. She was febrile, and there was a lemon tinge in the skin. Apart from a tumour in the lower abdomen, thought to be a fibroid, and a precordial murmur no other physical signs were detected. The haematological findings are shown in the table.

Microscopical examination of the blood showed the presence of the densely staining microcytes usual in acholuric jaundice, along with large numbers of reticulocytes and nucleated red cells. Free HCl was found in a test meal. A diagnosis of a haemolytic crisis in acholuric jaundice probably of the so-called acquired type was made.

### COURSE OF THE ILLNESS

A transfusion was given but failed to affect the haemolysis as did a further transfusion three weeks later. Parenteral liver treatment was tried without effect. Splenectomy was therefore carried out, a small spleniculus being also removed. Gall stones were noted to be present. The patient's blood was now found to agglutinate the red cells of two donors of her own group (O), but a compatible donor was found and a further transfusion given after the operation.

Although the spleen had been impalpable it was seen to be enlarged on removal, the weight being 500 grammes. The cut surface was a uniform dark red colour, the Malpighian bodies being invisible. Microscopical examination showed the usual feature of acholuric jaundice—namely, well marked engorgement of the pulp with red cells, the Malpighian bodies were small, and no pigment deposits or Gandy-Gamna nodules were seen.

Table showing the Blood Picture in a Case of Failed Splenectomy

TF direct Van den Berg's test refer to the immediate reaction.

Following the splenectomy the patient was worse the red cells becoming deeper and of the obstructive type for a short period with some swelling of the left leg and pleural fluid pain in the chest. Pyrexia persisted and there was no cessation of haemolysis but there was an increase in the reticulocytosis. The haemoglobin rose to 45 per cent but soon fell back below 30 per cent.

Eventually after four months in hospital during which splenectomy three transfusions and liver therapy had failed to arrest the haemolysis it was decided as a last resort to explore again in search of a spleniculus. This was done but no spleen was found. The gall bladder and the pelvic tumour which proved to be an ovarian teratoma were removed. No transfusion was given. Unexpectedly the haemolysis ceased immediately the signs of toxæmia disappeared the temperature settled and the blood began to return to normal complete recovery ensuing.

## ULTIMATE BLOOD CHANGES

Twenty six days after the last operation the excessive haemolysis having ceased the increased fragility was still present. It was not tested again for sixteen months when it was found to have become normal. The use of a quantitative technique and washing the red cells revealed no defect. Price Jones curves were constructed from blood films taken before the splenectomy and transfusions (25/1/36) and after the establishment of normal fragility (18/10/37) and are shown

in the accompanying chart. The mean corpuscular diameter was originally normal but the variability was very high.

After recovery the mean diameter was found to be above the normal range (8.136  $\mu$ ) but the variability was normal and

Chart showing the Price Jones curves before splenectomy and transfusions and after the establishment of normal fragility.

no large megalocytes were found. The mean corpuscular volume (98 c $\mu$  on 18/10/37) was also slightly increased with a normal mean thickness (19  $\mu$  calculated). Apart from these changes and an increased platelet count the blood picture has become normal.

## THE OVARIAN TERATOMA

The ovarian teratoma consisted of a dermoid cyst containing some pellets and flakes of sebaceous matter and hairs. The following tissues were present in the wall: squamous epithelium, sebaceous and salivary glands, hairs, intestinal wall including mucosa, lymph follicles, muscular tissue, nerves, and nerve ganglia. No splenic tissue was found. Degenerative changes with an inflammatory exudate and polymorph infiltration and plasma cell foci were present in places. A bacteriological examination was not made, as its possible significance was not apparent at the time.

The gall bladder contained numbers of dark coloured faceted calculi. Except for pigmentation of the epithelium the wall showed no changes, but the cystic lymph gland contained considerable deposits of brown pigment, conspicuous to the naked eye. Microscopically these were found to be associated with proliferated endothelial cells lining the sinuses, the pigment gave a negative reaction for iron, and was presumably of biliary origin.

## Discussion

In attempting to explain the train of events in this case the usual limitations of uncontrolled clinical material of this type restrict the drawing of conclusions, but the most probable explanation, so far as it goes, is that some substance was being absorbed from the ovarian teratoma and was, directly or indirectly, one of the causes of the haemolysis. Its mode of action can only be a matter of speculation, and we are unable to define the relation of the excessive fragility to the condition. It was present throughout the haemolytic period, persisted afterwards when excessive haemolysis had ceased, but eventually disappeared and the mean corpuscular diameter, which had been normal, became abnormally high. The findings suggest a change from spherocytosis to a flatter cell of normal thickness and increased diameter, but it is of interest that Hawksley (1936), as the result of a study of the red cells, suggested that familial acholuric jaundice could not at present be regarded as a primary defect either of erythropoiesis or of splenic function, and Vaughan (1937) concluded that increased spherocytosis is not the fundamental abnormality present in the red cell.

There are certain other possibilities which appear less probable. The removal of the gall-bladder at the second operation might be related to the successful result. No significant changes were found in the gall-bladder wall, and although calculi were present they are also present in a large proportion of cases of acholuric jaundice, and whether they are left or removed at operation does not appear to influence the result so far as haemolysis is concerned.

With regard to alternative diagnoses the condition most closely resembling this case is Lederer's haemolytic anaemia. The following are against this diagnosis: (1) the failure to respond to transfusions, (2) the excessive fragility and other red cell changes, (3) the prolonged period of haemolysis (four to six months), (4) the histopathology of the spleen, which was that of acholuric jaundice. While these may appear to be good reasons for differentiation, we discuss this question further below.

The absence of a previous history and a family history (two daughters were available for fragility tests and both were found to be normal) is usually accepted as evidence that the case is of the acquired type of excessive red cell fragility, although the existence of the acquired type is still questioned (Vaughan, 1936). There is some evidence that the two types exist but we have no definite conclusion to offer on this question. As excessive fragility

persisted for some time after cessation of the haemolysis an additional factor or factors (besides the spleen) must have been present during the crisis.

## Classification of the Haemolytic Anaemias

The classification of the haemolytic anaemias is still unsettled, chiefly owing to lack of knowledge of their aetiology. It is not even clear whether cases showing increased fragility should be classified with those in which fragility is normal. Of Lederer's six cases (1925, 1930) the fragility is mentioned in three, and in these it was normal. Other writers have disregarded this point, and many cases showing increased fragility have been classified as Lederer's haemolytic anaemia.

Lederer did not discuss the differentiation of his cases from the crises of acquired acholuric jaundice. O'Donoghue and Witts (1932), in dealing with differential diagnosis, differentiate Lederer's anaemia from acholuric jaundice by the absence of family history and the brief duration, and from chronic acquired haemolytic anaemia by the acute febrile course with leucocytosis and signs suggestive of infection, but they provide no means of distinguishing it from haemolytic crises in acquired acholuric jaundice.

We have mentioned above four reasons for differentiating our case from Lederer's haemolytic anaemia, but in the latter condition has not yet been adequately defined we are unable to estimate to what extent these differential criteria are valid. We make the following comments regarding them.

1 Failure to respond to transfusion—Some cases described as Lederer's have failed to respond to transfusion, and some cases of acholuric jaundice (Scott, 1935) have apparently responded well. One of us has seen an acute haemolytic crisis apparently respond satisfactorily to a transfusion, but when recurrence took place, over a year later, transfusion failed. Response is apparently variable in either condition and even in the same individual.

2 Excessive fragility—This has already been discussed. Other red cell changes have not yet been adequately defined in Lederer's.

3 Duration—According to O'Donoghue and Witts Lederer's disease is of a self-limited character, tending to death or complete recovery within a period usually of a few months. The value of this criterion is nebulous.

4 Histopathology of the spleen—This is not yet established in Lederer's anaemia, as in none of his six cases was the spleen available for examination.

It is apparent that the differentiation of the two conditions is by no means clear, if indeed Lederer's anaemia is a distinct entity. In the absence of any record of increased red-cell fragility in Lederer's original cases, haemolytic crises showing this feature appear to us to be best classified in the acholuric jaundice group until more is known of the aetiology. It is perhaps of some interest that Harvey and Janeway (1937), in describing three cases of haemolytic crises apparently due to sulphanilamide, comment on their striking similarity to Lederer's anaemia.

## Treatment

The first treatment usually adopted in haemolytic crises appears to be transfusion, in spite of its special risks. When this fails splenectomy has to be considered. Some of the cases quoted and the new one recorded indicate that an alternative sometimes exists and our case shows that this alternative may be effective where the other two methods fail. It would seem reasonable to suspect the presence of an infection or other toxæmia in any case of acholuric jaundice showing a haemolytic crisis, but that

there are other factors in the production of the latter is apparent from its rarity compared with the frequency of toxæmia.

Failed splenectomies have been recorded not only in the apparently acquired type of acholuric jaundice but also in the hereditary congenital type (Freund 1932) and there seem to be no data available to show whether failure is commoner in one type or the other. It is doubtful at present therefore whether splenectomy should be regarded with greater favour in the familial congenital type.

### Summary and Conclusions

A case of acholuric jaundice with a hæmolytic crisis is recorded in which splenectomy failed to cure the hæmolytic crisis.

Recovery followed the subsequent removal of an ovarian cyst.

From a consideration of this case and others from the literature it is apparent that splenectomy does not always cure or prevent hæmolytic crises in acholuric jaundice and where radical treatment is necessary splenectomy is not invariably the method of choice.

Evidence suggesting that toxæmia may act as one of the precipitating factors in producing a hæmolytic crisis and that the latter may be cured by removal of the toxæmia, is discussed.

We are indebted to Mr P. McEwan in regard to the surgical procedures mentioned.

F. Hamburger (*Disch. Tuberk. bl.* March 1938 p. 53) points out that almost every tuberculous patient has tuberculous bronchial glands; there is however a narrower and more definite clinical entity occurring chiefly in infants under 2 years old. The general symptoms include a subfebrile daily temperature with a slight rise at night, lassitude, night sweats, and anorexia. Local symptoms are due to compression of the bronchi or trachea and give rise to a high pitched metallic cough and expiratory stridor. Similar symptoms may be due to mediastinal tumours or to acute bronchitis and these conditions must be ruled out. Physical examination is of little value in the diagnosis of tuberculous bronchial glands. The tuberculin test must always be carried out. A negative result is proof of the absence of tuberculosis. An increased shadow round the hilum may be due to causes other than enlarged bronchial glands; its presence in a radiograph must be interpreted together with the other clinical data. A high blood sedimentation rate of 30 to 40 millimetres or more after an hour is in favour of active tuberculosis; a lowering of the rate is of good prognostic significance.

## Clinical Memoranda

### Fragment of Needle in Foot

(WITH SPECIAL PLATE)

The following case history presents some points that may be of interest.

#### CASE RECORD

A man consulted me on March 15 1937 complaining that for the past two years he had suffered recurrent attacks of pain in the right ankle joint. Latterly this symptom had increased in severity and on exertion the right foot became swollen.

On inspection the condition appeared to be due to chronic arthritis of the ankle joint. On examination revealed a small fragment of a needle in the soft tissues below the head of the tibia (Fig. 1). Under local anaesthesia a Sennet's incision was made into the sole of the foot down to the location of the foreign body using the fluorescent screen. The incision was extended leaving the cannula in position. A fluoroscopic photograph (Fig. 2) was then taken by Dr McDougall. The case is as follows.

A piece of the end of a needle about half an inch long was visible close to the bone in the plantar aspect of the head of the tibia. In the dorsal plantar view the foreign body is seen in the centre of the foot and about a quarter of an inch from the joint formed by the os calcis and the cuboid. A needle indicator in position showing the relation of this guide to the foot is as follows.

Under local anaesthesia a vertical incision about three inches in length was made in the sole of the foot. Using the cannula as a guide the dissection was carried through the plantar aponeurosis and deeper structures down to the head of the os calcis. The fragment of needle was found under the periosteum. The distal end of the cannula was situated about a quarter of an inch from the foreign body.

Points of interest are (a) the use made of the cannula as a guide (b) the patient had no history of a needle having entered his foot or any other part of his body.

Auckland, New Zealand.

### Ischio-pubic Osteochondritis with Report of a Case

(WITH SPECIAL PLATE)

This uncommon condition has only recently been recognized clinically. Attention was first drawn to it by Van Neck in 1924. Since then a few cases have been described in America and on the Continent but none has been reported in the British Isles. Probably it does occur with some rarity and only needs a wider recognition of its clinical and radiographic features.

The condition arises before the union between the ischium and pubis is complete. This occurs between 8 and 10 years of age. The case described below was that of a boy 8 years old when first seen. He had been complaining of pains in his lower limbs for four years. In Durham's series the average age of the five patients was 7½ years. Either sex may be affected. The condition may be bilateral or may only affect one side. It is a non-suppurative osteochondritis allied to the disturbances in growing areas met with in Perthes's and Osgood-Schlatter's disease. Durham thought that trauma might be a causative factor in some of his cases. There was no definite severe injury in the present case but the boy was apt to trip and fall easily, and this may have been a factor.

The child is usually brought to the doctor on account of a limp and of pains in his lower limbs, referred about the hip-joint. The severity varies, in some children the disability is slight, but in others the child may be acutely ill. Two of Durham's patients held the hip flexed and had a temperature of over  $102^{\circ}$ . On rest in bed the acute symptoms rapidly subside. In bilateral cases all the symptoms may be referred to one side. Examination usually shows some spasm in the adductor muscles, causing a limitation of abduction, extension, and rotation of the hip-joint. Some thickening is to be felt over the ischio-pubic junction, and in the acute stage tenderness is present over the swelling.

Treatment consists in rest in bed till all spasm has disappeared. This will take less than six weeks, although the radiographs will still show the rarefaction and swelling at the ischio-pubic junction. Gradually the bony condition returns to normal.

#### CASE RECORD

In the present case the mother stated that for four years the patient a boy aged 8 was easily tired. After walking about a hundred yards he would complain of pains in the calves; he also tripped and fell without apparent cause. The symptoms were not always present, but varied from day to day.

The boy was pale, of average height and weight, and had large and unhealthy tonsils. Nothing abnormal was noted on inspection. Movements at the hip joints were full, with the possible exception of a slight diminution of internal rotation in the left hip. Palpation of the ischio pubic ramus revealed a slight thickening in the descending ramus. This swelling was not tender. The reflexes and sensation were normal. An x-ray examination showed swelling and rarefaction at the ischio pubic junction typical of osteochondritis. The condition was present on both sides, but was more marked on the right side (see Plate).

It was thought that the septic tonsils might have been a factor in the boy's pains and condition. The tonsils were accordingly removed by dissection. When seen six weeks later the patient was much improved in every way, but he was not yet allowed to exert himself. A radiograph taken at this time showed a lessening of the rarefaction, but the bone was not yet normal.

GEORGE D F MCFADDEN, MCh, FRCS,  
Belfast Ulster Hospital

### Clubbing of Fingers and Toes associated with a Congenital Lung Cyst

(WITH SPECIAL PLATE)

The following case appears to be interesting enough to be placed on record.

#### CASE RECORD

A commercial traveller aged 50 was referred to the outpatient department for investigation on account of glycosuria. He gave no history suggestive of diabetes mellitus and the urine did not contain sugar, acetone or diacetic acid. Blood sugar was found to be 0.085 per cent two hours after a meal containing carbohydrates. On closer interrogation the patient stated that he had been taking large doses of aspirin for headaches. There was no history of previous illness, but since 1917 when he was gassed in France he had developed some cough with a little sputum. This had never been blood-stained; there was no dyspnoea on exertion and no other symptom of cardiovascular embarrassment.

On examination the patient appeared to be a normal healthy man rather younger than his age. He was not cyanosed. Attention was immediately called to the fingers which displayed a noticeable degree of clubbing with nails curved like an inverted watch glass and of a moderately livid tinge (Fig 1). It was soon discovered that the toes showed a

similar abnormality (Fig 2). The patient repeatedly stated that he had always had large nails and remembers quite distinctly his mother telling him that they had been so since childhood. No information was obtained as to whether this peculiarity had occurred in other members of the family. The

FIG 1—Photograph of left hand showing a noticeable degree of clubbing.

FIG 2—Photograph of right foot showing clubbing of toes.  
The patient is an only son and lost his father when still very young. His mother lives in Canada.

The heart was not enlarged and the sounds were clear. There were occasional extrasystoles without subjective distress. An electrocardiogram was normal except for occasional ventricular extrasystoles. His blood pressure was 130/80. The lungs expanded normally and on percussion gave a

slightly hyperresonant note. On first examination a small group of crepitations were heard over the right interscapular region; on this finding was not confirmed in subsequent examinations. A radiograph of the chest showed a moderate degree of chronic bronchitis and emphysema such as is often found in patients who have been gassed. The sputum was negative for tubercle bacilli and the sedimentation rate was 6 mm. at the hour. A blood count showed normal values for red blood cells, haemoglobin and white blood cells with normal distribution.

The right lung was then injected with lipiodol by the intra-axillary route and a bronchogram was taken (see Plate). This led to the discovery of an unsuspected cavity about half an inch in diameter in the right upper lobe. The distribution of the lipiodol was normal in the other bronchi. Unfortunately the patient refused to undergo injection of the left lung on account of a mild iodism after the first injection.

### DISCUSSION

Two points are obviously of interest in the diagnosis of this case: first what is the nature of the cavity shown in the bronchogram and secondly can any relation be established between the condition of the lungs and the clubbing of the fingers and toes? The most probable explanation of the cavity is that it is a lung cyst. There is no evidence either local or systemic of tuberculosis or of non-tuberculous lung infection. The outlines of the cavity are not shown in the chest radiograph. As to the second point it is evident that no recent infective or other pathological process could explain the clubbing of the fingers and toes as this occurred very early in childhood. A causal relation might with the greatest reservation be assumed with a congenital lung cyst especially as we do not know whether a bronchogram of the left lung would have shown a similar and perhaps more extensive process. But I would like to stress the words "with the greatest reservation".

One fact certainly emerges from the study of this case—that is the importance of bronchography. I think it is worth while emphasizing this point as in a recent paper Dr Seaton (1938) stated that clubbing of fingers without an apparent cause is not uncommon. I venture to suggest that this statement is rather far-fetched and that the condition would be found to be quite infrequent provided the cases were investigated thoroughly enough and a chest was not dismissed as normal merely on clinical and radiological evidence.

As I myself am presenting a case of congenital clubbing of the fingers and toes it is obvious that it is not my wish to deny the existence of such a condition. The familiarity in some cases as reported in Dr Seaton's very interesting paper would indeed be sufficient to establish it firmly.

### SUMMARY

A case of congenital clubbing of fingers and toes is described in which a radiograph of the chest did not show any marked abnormality while a bronchogram revealed an unsuspected cavity in the right upper lobe. The nature of this cavity believed to be a lung cyst is discussed with its possible relation to the clubbing of the fingers and toes. The importance of bronchography in the diagnosis of obscure cases is emphasized.

I wish to express my gratitude to Dr Ernest Fletcher for permission to publish this case and for helpful advice and criticism.

E. MONTUSCHI, M.D.

## Rupture of an Ovarian Dermoid

(WITH SPECIAL PLATE)

So uncommon is the rupture of an ovarian dermoid that the following case seems of sufficient interest to be recorded.

### CASE RECORD

A single woman aged 34 admitted to Charing Cross Hospital as an emergency under the care of Mr R. A. Fitzmaurice on whose behalf I saw the case and by whose permission these notes are published. She was seized with a sudden sharp pain all over the abdomen but felt more severely in the right iliac fossa. She was emphatic that it was not of a colicky nature and in no way resembled colic. She stated that the abdomen was sore to the touch. Two days previously she had vomited and on the onset of the acute pain there had been a feeling of fullness in the abdomen with retching but no recurrence of the vomiting. The bowel habit over many years had been constipated with a definite feeling of obstruction to the passage of the faeces. There was no disturbance of micturition. Her menstrual period which began at the age of 17 had been regular although painful until an untimely menopause at the age of 40. The only point of interest in the past history was a bilious attack two months prior to admission—since a hard passed up to the liver at the time of operation revealed the presence of gall stones.

On examination the patient did not appear ill. Her temperature was 99° the pulse 116 and her tongue clean. The abdomen was diffusely tender and rigid more so below the umbilicus than above and more to the right than to the left of the midline. No abdominal mass was palpable. The rectum contained a quantity of constipated faeces and a mass of similar consistency in the pouch of Douglas was thought wrongly to be faecal material in the sigmoid colon. A diagnosis of mild unlocalized peritonitis was made probably not of appendicular origin. Operation was advised and accepted.

A lower paramedian incision was made and the peritoneal cavity was found to contain fluid resembling sebaceous material of which some three pints were removed by suction. The source was found to be a collapsed left ovarian cyst the site of rupture through which hair was protruding was on the right hand side the solid portion occupying the pouch of Douglas. The cyst was removed appendicectomy performed and a drain left down to the pelvis. The tumour measured some eight inches in diameter and its contents are shown in the photograph here reproduced (see Plate). *Staphylococcus albus* was grown on culture of the fluid. Dr H. W. C. Vines reported as follows upon the specimen: "A multilocular simple dermoid cyst presenting no unusual features." There was no drainage and the patient made an uninterrupted recovery being discharged on the fourteenth day after operation.

K. L. JAMES, M.S., F.R.C.S.

Charing Cross Hospital, W.C.2

Surgical Registrar

H. Mai (*Münch. med. Wschr.* March 18 1938 p. 399) reports on the use of convalescent serum in the treatment of acute anterior poliomyelitis in children. His statistical survey embraces 375 cases of which 145 were treated with convalescent serum while 190 had no serum. The serum had no effect when given in either the pre-paralytic or paralytic stage. The mortality among the children treated with serum was higher than among the children who had no serum but this was probably due to the fact that no recourse to serum was frequently had in very severe cases with signs of respiratory paralysis. On the whole the serum proved neither useful nor harmful.

## Reviews

### THE PECKHAM HEALTH CENTRE

*Biologists in Search of Material* An Interim Report on the Work of the Pioneer Health Centre, Peckham (Pp 104 2 plates, 3 plans 2s net) London Faber and Faber 1938

Dr Scott Williamson and Dr Innes Pearse describe themselves merely as 'Biologists in Search of Material,' but their humanitarianism, like cheerfulness, will "keep breaking through." Such a title for their second interesting and stimulating report on the work of the Peckham Health Centre errs on the side of undue modesty, especially in view of their admission that visitors to the centre are impressed by finding "a socio-medical institution throbbing with movement and gaiety." However, in justification of the title they have chosen, they lead off with an introduction based on broad biological principles, which is followed by Mr J G S Donaldson's pertinent commentary from the layman's point of view as to the importance of the experiment.

It is by this time fairly widely known that the centre takes the family as the unit for investigation, believing that only in this way can proper insight into the problems of the individual be obtained. To this rule there is only one, and an important, exception—the fiancé(e) of a member of the family. On the social side the opportunities for neighbourliness are an important asset of the centre, and one which has its medical aspects (has not Dr Stephen Taylor recently written convincingly on the causes of the 'Suburban Neurosis'?). Here we are naturally more concerned, however, with the valuable data of a more immediately medical sort which have been accumulated. It is perhaps surprising that out of 1,666 individuals about 180 were found in the course of routine examination to be suffering from major maladies, very few of whom were attending a doctor. It is less surprising, but rather depressing, to learn that minor maladies were ten times as frequently found—more than one often being found in the same individual. One clinical observation which is worth emphasizing is the frequency with which infestation by worms was found in those who persistently had less than 100 per cent of haemoglobin. The findings at the centre agree with those of Professor Stanley Davidson that many women of the working class are on the borderline of iron starvation. The account of 'devitalization' in its two forms of 'hypotonia' and 'dystrophy' (to adopt the authors' nomenclature) is full of valuable and suggestive hints for all medical men, as is the discussion of the causes of malnutrition in those apparently adequately supplied with food.

Two other points in the report are worthy of comment. Between the two states of health and disease there is a considerable "no man's land" in which the individual may feel well but is using up the powers of compensation with which his body is endowed. The authors label this, not too happily we think, 'well-being', well seeming would perhaps be more accurate. The importance of preventive treatment at this stage is obvious: the opportunities of giving it are few, except under such conditions as obtain at a health centre like this. The other point is the avoidance of *advice*—the facts are so presented to the individual that he can form his own conclusions as to the right thing to do. Herein they follow the method of certain schools of psychotherapy. They realize that individuals from infants to old people resent or fail to show any interest in anything initially presented to them

through discipline, regulation, or instruction." This, alas, is often only too true!

It may be said that this is the report of enthusiasts, well, enthusiasm is necessary to carry through such a task. Visionaries, perhaps—but such visions have a way of coming true. In any case, we recommend the reading of this report and, still more, a visit to the Peckham Health Centre as an admirable tonic for any doctor who in moments of depression feels that his is the task of Sisypheus.

### OBSTETRICS AND GYNAECOLOGY, 1937

*The 1937 Year Book of Obstetrics and Gynecology* Obstetrics, edited by Joseph B De Lee, AM, MD Gynecology, edited by J P Greenhill BS, MD, FACS (Pp 704, 137 figures 2 50 dollars, 10s 6d, postage 6d) Chicago Year Book Publishers, London H K Lewis and Co 1938

The Chicago Year Books of Medicine have now reached their thirty seventh edition and are well known to, and appreciated by, English readers, the need for such a compendium as a yearbook is indubitably growing every year in all departments of medicine, for neither practitioner nor specialist can hope to establish direct contact with the new ideas which are being promulgated in such profusion and in many languages. The chief difficulty of the busy man is that he has not enough leisure to sift out the new ideas from the mass of verbiage in which they not uncommonly lie buried, he looks to a yearbook to do this for him. And further, not all new ideas are improvements on the old, therefore the reader requires critical guidance in evaluating the new departures that are presented to him. *The 1937 Year Book of Obstetrics and Gynecology* edited by Professor De Lee and Dr Greenhill, is exemplary in all respects. More than three hundred papers are summarized more or less succinctly, and to all but a very few there is appended an editorial comment which the reader will find extraordinarily helpful. The comments are attractively written and even when brief are never perfunctory. As an example of American terseness may be quoted the verdict on a communication in the well-known Scandinavian *Acta Obstetrica* ("OK Ed"). Another of Professor De Lee's comments, this time on the "Endocrine Background of Toxaemia," is worth reproducing: '(Perhaps the author is groping towards the light of truth. Good luck! Ed)'. A series of nineteen papers dealing with analgesia and anaesthesia in labour are of especial interest, and incidentally are the subject of the longest and raciest editorial comment in the whole book. Beginning with 'Mrs Pithecanthropus Erectus,' who had no more pain than the animals her man fought for food, the editor deplors the effect of "civilization (?) " in making women intolerant of pain, but relates with approval the case of the young primipara who refused an anaesthetic on the ground that 'she wanted to drink deep of life,' which she regarded as a great adventure. The conclusion reached is that there is no completely harmless anaesthetic or analgesic and that women must pay a price for their relief from pain.

In the gynaecological section will be found notes of a series of twelve papers dealing with vaginal infection by trichomonas which will be of interest to the pathologically minded gynaecologist. Senior readers of the section will note with interest the revival of an old method under a new name, introducing steam into the uterine cavity (utero-causis it was called) had a short and undistinguished career in the early years of the present century but was soon abandoned. It appears to be now staging a comeback under the name of vaporization.

Many papers dealing with endocrinology are brought to the attention of the reader, but the most useful feature of this section is a series of four charts the work of Dr Greenhill depicting the functional activities of the pituitary and ovarian hormones throughout the menstrual cycle, pregnancy and the puerperium. Dr Greenhill has come as near to explaining this very complex subject as the human mind can be expected to get and if the reader cannot master it with the aid of the charts he should give it up as a bad job and hope that time will bring simplification.

### SHORT-WAVE DIATHERMY

*Short Wave Diathermy*. By Tibor de Cholnoky. (Pp. 110, 5 illustrations, 20s. net.) New York: Morning Side Heights Columbia University Press; London: Humphrey Milford Oxford University Press, 1937.

In this book Dr Tibor de Cholnoky presents a useful survey of the subject up to its present state of development. As the majority of publications on short wave diathermy have been in foreign languages an outline of the subject in English with accounts of the experimental work which has been done is timely. It opens with a brief and simple account of the physical aspects of short wave diathermy recapitulating the essentials of electric heat production. The author is chiefly concerned with the medical side of the subject and does not discuss in detail the physics of the production of short waves or the technical details of apparatus and for these the reader must consult standard textbooks.

Much interest has been aroused regarding the possible action of short waves on bacteria and various workers hoped that a lethal or at least an inhibitory effect on their growth would be produced. By experiments *in vitro* Schlöphake and Haas found that streptococci were killed and tubercle bacilli at body temperature were killed after some hours exposure. The results of other workers have been inconclusive and contradictory. Differences in apparatus used and the impossibility at present of measuring with accuracy the intensity of the electric field are factors accounting for variation in results. Experiments on plants seem to show that short waves have an accelerating effect on growth and sprouting and there is scope for further research in this direction.

After chapters on wave lengths and on clinical technique and general principles comes Part V on the clinical applications of short wave diathermy. Here the most outstanding effects described are those first reported by Schlöphake in the rapid and successful treatment of boils and carbuncles. The author also cites Schlöphake's encouraging results in forty cases of lung abscess in which progress was recorded by radiographs and laboratory tests. Dental conditions too further work should be interesting and valuable and in bone and joint injuries short wave diathermy has proved its usefulness. The earlier workers with short waves expected that in addition to local heating effects short waves would be found to have "specific" effects varying with wave lengths etc. The author believes that at present there is no evidence to support any claim for the existence of specific effects and regards short wave diathermy entirely as a form of heat therapy the beneficial action of which is due to the intense and lasting hyperaemia it provokes.

Dr Tibor de Cholnoky has written a cool and level-headed review of the work achieved by workers with short wave diathermy. If the book is lacking in the freshness and enthusiasm of books written from personal experience it is the verdict of an impartial observer and as such is to be valued. There is an ample bibliography.

### PROGNOSIS OF ACUTE DISEASE

*Les Eléments du Pronostic dans les Maladies Aigües*. Notes de Pratique. By A. B. Martan. (Pp. 80, 20 fr.) Paris: Masson et Cie, 1937.

This study of the prognostic factors in acute diseases by Professor Martan will be found helpful to many. Never prophesy unless you know is in medicine a counsel of perfection for we are daily called upon a prophesy in matters wherein certainty is difficult if not impossible. The author does not accept the view that the public is more willing to excuse an error of diagnosis than one of prognosis; rather the truth is that the public can judge the latter more readily than the former. An error in diagnosis is a matter on which only another medical man is capable of expressing an opinion but all the world can recognize an error of prognosis. A medical man can shelter his reputation by guarded answers to the latest enquiry put to him but if he considers the interest of his patient and of medical science he must know the signs which forecast the course and the issue of the malady.

Professor Martan considers that it is in acute diseases that prognostic errors are most easily made and have the most serious consequences. He starts by discussing the prognostic factors in typhoid fever because the principles apply with minor differences to the other acute diseases. This recalls Osler's remark that he could teach all the general principles of medicine from typhoid fever. Fortunately for the public cases of typhoid fever are much less common than they were. But in consequence medical students qualify and go out into the world with a much less adequate knowledge of a disease which still crops up unexpectedly and which calls for prolonged and skilful treatment however expectant in type. There is therefore abundant justification for pride of place to be accorded to this disease in the book before us. Subsequent articles deal with lobar pneumonia, bronchopneumonia, diphtheria, scarlet fever, meningitis, endocarditis and pericarditis. It is a sign of the importance attached to a study of rheumatism at the present time that one third of the book is devoted to the last two subjects. The whole book is practical, lucid and interestingly written.

### ORAL SURGERY

*Surgical Diseases of the Mouth and Throat*. By Earl Calvin Padgett, B.S., M.D., F.A.C.S. (Pp. 807, 3s. figures 42s. net.) Philadelphia and London: W. B. Saunders Company, 1938.

This book will have an appeal to both surgeons and dentists but the author's ambition has been even wider since he tells us in his preface that he has made an attempt to present material which will be of interest to certain special practitioners such as the nose and throat specialist, the dermatologist or radiologist who see conditions which in certain instances overlap from their field into that of oral surgery. A large field is covered as may be exemplified by the fact that there are chapters on fractures and dislocations, dental extraction, inflammatory diseases of the antrum and articles on radiation therapy and speech training in cases of cleft palate. The author has had the assistance of a number of colleagues to whom he refers in the preface where he also makes a remark which reminds us of a not unfamiliar problem in other branches of surgery. With Dr Sheldon and Dr Louis James there took place considerable discussion concerning the dividing line between those cases which should be submitted to the orthodontist and those which should be managed by the oral surgeon. The field covered is even wider than the title implies since

Chapter XVIII deals with inflammation and diseases involving the neck, and accounts are given of tuberculous lymphadenitis and oesophageal diverticulae. Diseases of the normally placed thyroid are not included, but lingual goitre and tumours and cysts of the thyroglossal tract come within the scope of the book. Clefts of the lip and palate are taken up in much detail and are well done, and this section constitutes one of the best in the book.

There is a brief account of the development of the modern operation for trigeminal neuralgia in which we should like to have found a reference to Sir Victor Horsley, who in December, 1890, attempted sensory root section for the condition, whereas the Spiller-Frazier operation was developed between 1898 to 1901. The author states the subzygomatic route for alcohol injection to be the safest and best. Few neurosurgeons would agree, however, this route having been almost universally abandoned for the Hartel approach from outside the angle of the mouth. While minor criticisms such as these apply to certain sections, we have nothing but praise for the work as a whole. It is easily read, the type being clear and the text divided into well-indicated sections, while line drawings and photographs amply illustrate it. This is a valuable work which in our opinion comes near to achieving the rather ambitious aim of its author.

### Notes on Books

Mr GUY BUTLER has all the qualifications to write a book on *Athletics and Training* (Adam and Charles Black, 5s). First as an athlete he was an amateur champion while still a schoolboy, and subsequently, in a long and distinguished career, all but achieved the highest honour in this branch of sport. He has more recently devoted himself to athletic journalism and has adopted the profession of trainer. He knows enough of the scientific side of the subject to know what he does not know, and he realizes the limitations of academic teaching for the aspirant to success on the track. Most books on training are full of ill-digested physiology or of pseudo-scientific jargon. Mr Butler has wisely stuck to his last, he has produced an eminently practical work in which every track and field event is dealt with technically. The subject of diet, upon which so much ink is unnecessarily spilt, is dismissed in a few lines. To illustrate how individual this detail must be the author states that when Nurmi beat the world's record for six miles his lunch antecedent to his effort consisted of almost all the things which theory forbids the athlete.

Dr DONALD PATERSON has thoroughly revised his book on *Sick Children: Diagnosis and Treatment*, for a third edition (Cassell and Co., 12s 6d), and this can again be recommended as a concise and practical account of modern paediatric practice. The section on anaemia, to which attention was drawn in a review of a previous edition, has now been brought into line with modern work on this subject and there are new accounts of acute and chronic sinus disease in childhood. Practitioners will find this a useful work, and the prescriptions freely scattered in the text are a valuable feature of the book.

*The Adolescent*, by ADA HART ARLITT, Ph.D., is published by the McGraw-Hill Publishing Company, price 8s 6d. This guide for parents in the upbringing of their children is essentially American for the Americans and so has less application in this country. It is pleasant, easy reading and on the whole full of common sense. The author makes no effort to penetrate to the deeper motivations of adolescent conduct which is probably commendable in a book intended for the laity, though it makes it appear rather superficial to the more initiated.

This is one of the many books which can safely be recommended to parents who wish to study the many problems of their growing children's lives.

The second English edition of *Poulsson's Textbook of Pharmacology and Therapeutics* has been prepared by Dr STANLEY ALSTEAD (Heinemann, 25s). The general character of the volume has not been changed, but the recent rapid advances in pharmacology have called for extensive revision. Important new advances such as sulphonamide and protamine-zinc-insulin receive notice.

## Preparations and Appliances

### A NEW PROSTHESIS

(WITH SPECIAL PLATE)

Mr A. WYNN GREEN (Wolverhampton) writes

The statistics concerning a one-eyed person are somewhat startling. Boissoniere gives the proportion in England as 1 to 162 persons, and this number must have been considerably increased by eye injuries during the war. Nor is the number decreasing to any extent, for, although many eyes are saved nowadays by the more advanced methods of surgery, the risks are being increased by motor accidents and by accidents in industry. The importance of any advance in the making of a prosthesis cannot be too much stressed: the one-eyed person is acutely conscious of his physical defect, and therefore suffers psychologically as well. Moreover, he is always at a disadvantage socially and in obtaining his livelihood. A skilfully devised, well-fitting prosthesis that can be worn with confidence, does not give rise to any eye irritation, and is within the reach of limited incomes: this seems to me a branch of ophthalmology well worthy of attention.

Considerable as are the advantages of the use of Snellen's reform eye, nevertheless it has this disadvantage—that it can be employed with success only in a socket of average size, unless (in cases where the socket is larger than normal) a base of porcelain, platinum, or gold is fitted, but this adds greatly to the cost.

A prosthesis recently devised by Mr L. B. Dibbens of Stafford has been used with satisfactory results by two patients of mine, who each had an eye removed because of growths, on the upper lid in one case and on the lower lid in the other. In neither instance was a satisfactory plastic operation possible, because the tumour had so extended as to destroy the lid structures. This particular prosthesis is clipped on to the inside of a spectacle frame, it consists of a transparent plate of amyl acetate, about 3 mm thick, on the orbital surface of which is painted with oils the representation of an eye, the upper and lower lids, and the surrounding skin (Plate, Fig. 1). The painting is done with the patient present, so that the eye may be accurately imitated for size as well as for colour of iris and of surrounding flesh. On the interior surface a small circular cavity is cut out, and into it is placed, to represent the pupil, a black bead which is covered with a section of an amyl acetate or calcium glass ball to form the corner. The whole plate is cemented or screwed to a tortoiseshell clip, which is fixed to the spectacle frame. Great care must be exercised in fixing the angle of the plate, and also in determining the size of the painted eye for refraction through the plate will alter the appearance of this considerably. The cost of the whole fixture is within the means of an ordinary hospital patient.

One of my patients, Mr S., had an epithelioma of the lower lid, destroying the surrounding structures. Excision was performed, with radium treatment by Mr Milnes Walker. Figs. 2 and 3 show him before and after fitting the prosthesis. Figs. 4, 5 and 6 illustrate the case of Mr F. who had a large sarcoma of the left upper lid, which had caused evulsion of the eyeball.

## INSULIN AND DIABETES THE PRESENT POSITION

SILPHEN PAGET LECTURE BY  
PROFESSOR BLST

The twelfth Stephen Paget Memorial Lecture under the auspices of the Research Defence Society was delivered on June 9 by Professor C H Best of the Chair of Physiology, University of Toronto who took as his subject Insulin and Diabetes. The Present Position Professor Best whose name is associated with that of Sir Frederick Banting in the discovery of the hormone is visiting this country for the purpose of receiving the Fellowship of the Royal Society.

The lecturer began by recounting the familiar story of the early work on insulin carried out in Toronto. He said that the leading part played by Banting in the initiation and prosecution of the research could not be over-emphasized and he also paid a tribute to the memory of Professor J. J. R. Macleod who made possible the rapid extension of the findings which Banting and he were able to obtain in the spring summer and early autumn of 1921. One of their first attempts to prepare insulin in quantity for clinical trial was made by administering millions of solution of a substance known as secretin to an anaesthetized ox. They thought that by this procedure they might exhaust the enzymes of the pancreas and then by performing a pancreatectomy render available supplies of insulin. They removed the organ and did make some active extracts from it but it was obvious that this was not a practicable procedure. They then resorted to the use of alcohol as an agent for the precipitation of inert material including the enzymes and their efforts immediately met with considerable success.

"One day we made a special lot of this material from the pancreas of one beast. The pancreas was removed aseptically. We tried the material on our colony of depancreatized dogs and then on ourselves. As the effect on Bunting and myself was only local we decided to go ahead with the administration to a severe case of diabetes. This was done on January 11 1922. The patient was one Leonard Thompson of Toronto General Hospital under the care of Dr. Walter Campbell. He was not a particularly co-operative patient and often threatened to spoil his interesting history by motor cycle accidents.

### From Early Experiment to Large scale Production

Professor Best showed portraits of another early patient—a little diabetic boy who played about in the laboratory before insulin was really available. His recovery under insulin was a matter of great pleasure to Banting and himself. Some people would go so far as to withhold insulin from a diabetic child—always the child of someone else; they are stories over the pain of others. Never yet have I come across anyone who had the courage of his convictions to a sufficient extent to withhold insulin from his own child.

The preparation of insulin was now on a secure scientific basis to facilitate large scale production. He gave a brief description accompanied by a colour film of the present methods from the bringing into the laboratories of the mass of ox pancreas to the final packaging of the sterile tablets. He also showed among other charts one illustrating the insulin content of the pancreas obtained from the animal at different ages. These findings had been obtained by Dr Scott and Dr Fisher. The content was much greater during intra uterine life than after birth and although this fact was not appreciated at the beginning, foetal pancreas was in fact used as a source of insulin for quite a long time. In detailing the work on the purification of insulin and the obtaining of insulin in crystalline form Professor Best mentioned that quite early in the history of this investigation the people who had the purest insulin found the greatest difficulty in pre-

paring crystals while those who had relatively crude insulin were exempt from his trouble. This was presumed because one or some closely related metal was present in the latter preparations (Scott).

[illegible]

## Mortality in Diabetes

Coming to the question of mortality in diabetes Professor Best said that the Ontario figures were of first interest because nowhere else in the world had insulin been at the disposal of everybody who wanted it since 1922. It was perfectly true that here as elsewhere the mortality from diabetes in certain age groups had not come down and might be going up. But a study of graphs showed that in the earlier age groups from birth to age 19 a sharp decline was obvious. The difference in the curve of mortality at under fifty and over fifty was also evident. Another curve showed that more and more insulin was being used in Canada every year. Even the slump years 1929-31 showed no dip in this upward curve proving that insulin was not a luxury. It meant that while the older practitioners did not easily take to insulin the younger ones trained in the more modern methods available used it to an ever increasing extent. While the medical student could not be expected to read the 10,000 publications that had appeared on the subject of insulin since 1922 he might be assured that he performed a most valuable function in spreading the knowledge of the modern treatment of diabetes and other diseases.

### Vote of Thanks

Sir EDWARD MELLANBY in proposing a vote of thanks said that it had been his lot to attend patients suffering from diabetes in pre insulin days. It was a mortification to feel that whatever one did one could only postpone the eventual issue for a matter of months. Nowadays one approached the diabetic patient almost with a jaunt, air knowing that one could turn him out to do his normal work within a few weeks. He was also one of the first

people in this country to make insulin, and he could appreciate the excitement which Banting and Best must have felt when they carried out their first experiments. One of the first two patients was a man who was brought in apparently in a moribund condition. He was six feet in height but weighed only six stone, and could not walk or stand. He left hospital after a month or two, and subsequently became managing director of a large steel company and was still living a completely healthy life. The discovery of insulin was only one of many advances in recent years which were the result of animal experiment. It was a curious situation that the greater the success of medical research in preventing or controlling disease the greater was the likelihood that the disease being prevented or controlled, the triumph would be forgotten.

The resolution of thanks was seconded by Dr R D LAWRENCE and supported by Lord LAMINGTON, who presided.

## MEYERSTEIN INSTITUTE OF RADIO- THERAPY

### GIFT TO THE MIDDLESEX HOSPITAL

Sir William Bragg, President of the Royal Society, opened on June 9 the Meyerstein Institute of Radiotherapy at Middlesex Hospital. This is a self-contained unit of four floors, made possible by the generosity of Sir Edward Meyerstein, a great benefactor to the Middlesex, who, having already contributed £30,000 towards the cost of the institute, announced at the opening ceremony his intention of giving the remaining £16,500 necessary to complete it.

#### Staffing and Equipment

In the institute all forms of radiotherapy are available for both in-patients and out-patients, both hospital and private. It is closely linked with the main hospital, and the resources of the Middlesex staff and laboratories are available for the service of the unit. The honorary director is Dr J H Douglas Webster, and there are five whole-time medical officers and a resident house officer, a sister, and six radiographers.

The most modern equipment both on the radium and x-ray side has been installed and elaborate protective precautions have been taken. The treatment cubicles are all provided with duct suction ventilation giving a change of filtered air twelve times an hour. Protective lead has been embodied in the walls to prevent stray radiations from reaching the corridors, and lead has even been put into the flooring of the second floor on which powerful tubes are installed, to prevent extraneous irradiation of the patients in the cubicles below. In every cubicle there is a two-way communication between patient and radiologist by means of microphones and loud-speakers. Two of the three cubicles on the ground floor contain shock proof x-ray tubes and the third is for telerradium. Here with 4 grammes of radium, mass irradiation is carried out at 8 cm distance. The radium when not in use is housed in a safe surrounded by ten inches of lead and the transference of the substance to the applicator is effected pneumatically through a flexible tube.

The first and second floors are devoted to x-ray therapy one for female patients and the other for male. The control of 200 kV shock proof tubes is by a multiple interlocking device so arranged that the apparatus as a whole must be switched on always in the same order—for example, no current can be conducted through a tube unless the appropriate cooling pumps are already working. In this way the plant has been rendered immune to abuse. The dose of x-rays to the patient measured either with an ionization chamber or by a calibrated clock is completed automatically by the closing of a lead shutter on the tube head and the interlocking is such that it is impossible for the patient to receive an over-

dose. There is also interlocking on the door of the cubicle, so that the moment the door is opened the lead shutter will close. On the first floor Siemens tubes cooled by oil are used and on the second floor Metropolitan Vickers tubes constructions which it is possible to dismantle completely, so that in the event of a broken filament or cracked target they may be taken to pieces, the faulty part replaced, and the whole reassembled. The couches and various centring and control devices are by Newton and Wright. The top floor is in part used for treatment by surface radium, with well provided mould and mounting rooms.

#### The Opening Ceremony

At the opening ceremony, in the absence of Prince Arthur of Connaught, the president of the hospital, the guests were received by Mr T B Money Coult, vice chairman. Sir William Bragg, before declaring the institute open, referred to the reputation which Middlesex had sustained for many years in research and advance in radiotherapy. He believed that Sir Edward Meyerstein got the inspiration for his present benefaction when he found that as a result of this work the word "inoperable" had been struck out in relation to certain conditions and "operable" substituted. The application of radium and kindred radiations to the cure of disease and alleviation of suffering was not misnamed a romance. He himself, although not a medical man had been in touch more or less with every phase of this progress. He remembered a day, many years ago, when he was at work in his laboratory and a young man entered and began to explain some of his theories concerning a magnetic detector. He was the future Lord Rutherford, who was afterwards to achieve unrivalled fame for his work on radio activity.

The new institute (Sir William Bragg continued) had an interest to the scientific mind beyond its obvious purposes. It was an instance of the application of science to human need and desire. A correspondent in the *Times* had been complaining of the vagueness of the customary interpretations of the word "science." He himself thought there was nothing better than the words which the founders of the Royal Society employed in 1660 when they met to consider the beginnings of the study of experimental science—"the improvement of natural knowledge." Since the Society was founded there had been a very great improvement, with tremendous changes in men's activities and powers. The improvement was due mainly to the extension of the natural senses through the development of instruments. With such extension a new world, unseen by the natural eye, came into view. Upon that unseen world the work of the institute depended. The radiations which it employed in its beneficent work were far beyond the range of human senses. They had effects of which humanity was glad to avail itself, but without the explorations of the unseen world nothing would have been known about them.

Before the ceremony closed Dr Hans Holfelder, a friend of the director, presented to the hospital on behalf of the medical faculty of Frankfurt University a portrait of Professor Röntgen.

C W Lavmon and H E Michelson (*Arch Derm Syph* Chicago, January, 1938) point out the immunity of certain areas of the body to the invasion of certain diseases and the rarity of lichen planus of the eyelids in particular. They report five cases and classify them into three types: (1) Typical lilac coloured pitted and scaling papules similar lesions occur elsewhere on the body. (2) An annular variety similar to that seen on the penis with the same type of lesion on other parts of the body. (3) A variety seen in brunette women aged about 30 in which the upper eyelids are discoloured with a brown, symptomless retiform eruption similar to that seen in a pigmented case of erythema ab igne. Their cases responded to treatment with x-rays and the injection of mercury bichloride.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 15 1938

## CANCER AND HEREDITY

The idea has long been abandoned that the 'cause of cancer' will be discovered and it is now recognized that a malignant neoplasm is the resultant of a number of factors and that these factors are themselves variable according to the site and nature of the growth. Recently much attention has been paid to the possibility of a heritable factor, and with the application of strict genetic analysis many interesting points have become apparent which though they cannot be claimed to make the problem of carcinogenesis simpler yet draw attention to some of its complexities. About 1908 J. A. Murray and others pointed out that the progeny of mice with carcinoma of the breast were more liable to develop a neoplasm in this site than those descended from mice not so affected, as a result of these observations Maud Slye suggested that the incidence of spontaneous cancer was due to a simple Mendelian recessive factor. This view was not generally accepted but it was necessary to secure strains of genetic purity before it could be put to the test. This can be achieved by repeated brother-sister inbreeding (strains which are pen-bred will not suffice) and after about thirty generations it can be shown that such a strain is genetically uniform. Since 1930 reports of investigations based on this method have been appearing and the findings of different workers may now be profitably reviewed.

In regard to spontaneous mammary cancer in mice it was shown that pure strains could be obtained in which the incidence in each strain was reasonably constant but this incidence varied between 0 and 85 per cent in different strains and they could not be divided into two groups—those of high and those of low incidence—which would have been the case had mammary cancer been due to the action of a single gene. In a 'high cancer' strain the extreme liability to mammary cancer is seen only in the female but if the males of the strain receive ovarian transplants (Murray<sup>1</sup>) or injections of oestrin (Lacassagne<sup>2</sup>) mammary cancer develops but males of a low-cancer strain do not so respond. Cramer and Horning demon-

strated that the administration of oestrin induced characteristic histological changes in the adrenal and pituitary glands of mice of ordinary mixed strain and that this change arose spontaneously in mice of a 'high cancer' strain. These changes and the liability to mammary cancer could be inhibited by the administration of the 'hydrocortisone hormone of the inferior pituitary'. In this particular strain it has been proved that there is no excessive secretion of oestrin but that there is an increased sensitivity of the tissues to this substance which when given to normal mice in enormous doses produces mammary hyperplasia and sometimes carcinoma. It is not yet known whether these endocrinal type changes in the pituitary glands of all 'high cancer' strains. All that can be deduced from these experiments is that the susceptibility to cancer of the breast in mice is determined by chromosomal factors but they throw no light on the factors controlling its incidence. That this is influenced by extra-chromosomal factors is suggested by the results of hybridization between pure strains of 'high' and 'low' cancer incidence. It was found that the incidence in the first generation tended to resemble that shown by the strain from which the mother was derived, such an inheritance is non-Mendelian and can only be explained by the transmission of some factor either occurring in the cytoplasm of the ovum during intra-uterine life or by means of the mother's milk. Bittner and Little have demonstrated that the incidence of cancer in female mice of a high-cancer strain is reduced if they are fostered by a mother from a low-cancer strain and the reverse would also appear to be true. Furthermore tubal ova from high-cancer strains have been transferred to uteri of low-cancer strains and after twelve months no cancers have developed in the offspring. The final experiment of fostering some of these transferred mice on a high-cancer strain mother has still to be performed but the conclusions of these experiments that the extra-chromosomal or maternal influence may tentatively be attributed as due to a breast-cancer producing influence obtained by the progeny from the milk of high-cancer mothers appear to be justified. What the nature of this milk-borne factor is remains to be discovered.

MacDowell and Richter found that the incidence of mouse leukaemia is also influenced by maternal extra-chromosomal factors but that they are not transmitted in suckling. According to Lynch and Andervont<sup>3</sup> the susceptibility of mice to lung tumours both spontaneously formed and induced by dibenzanthracene is inherited as a dominant characteristic. Lynch's work excluded the possibility of

a maternal factor, though it would appear that there is a modifying gene in the sex chromosomes. In animals other than mice the influence of heredity has been little studied, though Stark<sup>9</sup> found that in *Drosophila* some tumours are definitely sex-linked and hereditary. Goier<sup>10</sup> has emphasized the importance of an appreciation of genetics in relation to tumour transplantation. A tumour arising in a genetically pure strain of mice can be transmitted successfully to all other members of the same strain and to those hybrids in which certain dominant genes are present. Furthermore, if the tumour is transplanted to a host lacking these particular genes it regresses after a short while and immune bodies to the tumour cells are found in the blood. Nevertheless, as Phelps<sup>11</sup> and others<sup>12</sup> have demonstrated, these immune bodies are not specific to the cells because they are tumour cells but because they are cells genetically different from the host's, identical immune bodies being produced by transplanting the normal organs of animals of distinct constitution. It is owing to the lack of recognition of the influences of genes in tissue immunity that false hopes have been raised as to the possibility of producing anti-cancer sera, and these observations will have considerable bearing on all future transplantation experiments.

Turning to human cancer, it is at once apparent that selective breeding such as has been achieved in the laboratory can never occur, yet it is reasonable to suppose that the liability to cancer is associated with genetic factors in man as well as in animals, this has been demonstrated in such conditions as familial polyposis of the colon,<sup>13</sup> and Cramer's<sup>14</sup> statistical survey has revealed that the familial incidence of mammary carcinoma is exceptionally high. The cancer family of Warthin, in which forty-three carcinomata appeared in 300 members, has been much quoted, and though a recent report<sup>15</sup> suggests that the cancer liability is disappearing in the descendants all the observations are in keeping with cancer liability being associated with dominant characteristics. The immediate clinical application of these various observations appears to be related to the work of Cramer and Horning in which mice highly susceptible to cancer showed evidence of endocrinal imbalance and remained cancer-free after treatment with hormones antagonistic to oestrin. Already the male hormone is being used with favourable results in "chronic mastitis," regarded by many as a condition predisposing to cancer. If certain physical characteristics were

observed to be frequently associated with cancer of a particular organ, persons with these characteristics could be kept under observation and treatment be instituted at the onset of any suspicious signs. The difficulties and perils of such a course of action are considerable, though it is only along lines such as these that preventive measures in cancer can be developed.

## MEDICAL CO-OPERATION BETWEEN ENGLAND AND FRANCE

Though the bonds uniting English and French medicine are numberless, it is surely not invidious to draw special attention to one which is singularly well designed to meet present needs. It is the Association pour le Développement des Relations Médicales entre la France et les Pays Etrangers (A D R M). The fact that this body co-operates in medical matters with other countries than those of the British Empire adds to, rather than detracts from, its usefulness to any special country, for it is in a certain sense becoming a central exchange or telephone putting many people of many countries in touch with one another. The directing force of the A D R M, which in 1922 was recognized by the President of the Republic at that time as "reconnue d'utilité publique," is the well-known surgeon, Professor Hartmann, who has endeavoured, often in the face of great difficulties, to make Paris a Mecca for medical pilgrims of all nations in reality as well as in name. Behind him are Dr Mathe and a full-time assistant, Mademoiselle Hure, whom medical visitors to Paris find a living encyclopaedia. In her office in the Faculty of Medicine (Salle Beclard), 12, rue de l'Ecole de-Médecine, she is to be found every day between 9.30 and 11 and between 2 and 5 dispensing information in whatever language an inquirer addresses her. To appreciate her services, it has only to be realized that before they were available a foreigner coming to Paris to follow postgraduate courses had to run the gauntlet of multiple forms and regulations. First he had to attend at an office open only three times a week and for just two hours at a time, and then, if he had been successful in obtaining the necessary document, he had to tie himself off to some other office to pay his fees after being kept waiting in a queue for an unconscionably long time. Now all he has to do is to confide himself and his contributions to Mademoiselle Hure, who not only takes charge of all technical formalities but also gives invaluable advice on where to go and whom to see.

At the annual meeting of the A D R M held this year an interesting account was given of its

<sup>9</sup> *Amer J Cancer* 1937 31 252

<sup>15</sup> *Ibid.* 19 6 27 434

activities during 1937. An incoming stream of distinguished medical foreigners has been counterbalanced by an exodus of French apostles of medicine to different countries. Professors Abram and C. Richet to the U.S.A. and Mexico, Cunéo and Lereboullet to Italy, Fiessinger and Lian to Sweden, Sargent to South America, Baudouin to the U.S.A., Besançon to Portugal and Hungary, and Brumpt to the Near East. With the support of the French Foreign Office, the Association has promoted the exchange of numerous medical students of several countries with those of France. In the case of Czechoslovakia alone, a three-day visit of more than sixty doctors to Paris was organized last October, and special lectures and demonstrations were provided for them. A return visit will be paid to Prague in September of this year. It is no secret that only a few years ago Professor Hartmann's efforts to promote international co-operation in the medical field encountered considerable xenophobia on the part of the more excitable elements among the French medical students temporarily stampeded into believing that the development of the Paris school of medicine as an international centre would be to their detriment. The following statistics reflect to a certain extent this state of affairs. In 1929 there were as many as 144 foreigners registered as candidates for the University diploma. The corresponding figures for 1935 and 1936 were only forty-four and nine respectively, whereas in 1937 the registrations had risen to fifty. The figures for the State diploma in the same period follow the same curve, with twenty-seven and twenty-two registrations in 1935 and 1936 respectively, and as many as forty-three in 1937. Between 1936 and 1937 there has also been an appreciable rise in the number of foreigners attending postgraduate courses. There seems good reason therefore to believe that the hospitality and facilities provided by the Paris school of medicine for the foreign visitor are becoming more and more appreciated by him.

### THE RADIIUM INSTITUTE AND MOUNT VERNON HOSPITAL

The union of these two bodies is now complete. This means two things: in course of time expense will be saved by the elimination of duplicate services, but more important still will be the concentration of resources for the treatment of the sick, the prosecution of research, and the training of radiotherapeutists. For the moment the work of the two institutions will go on as hitherto, but use will be made of the resources of one body to supplement the other—thus the deep therapy plant at Mount Vernon will be used for the

patients of both. It is intended eventually to concentrate most of the work both on the therapeutic and research side at Mount Vernon where there is ample bed accommodation and good pathological and physical laboratories out to keep the outpatient department and offices in London. Negotiations are taking place between the Medical Research Council and the new body for the continuance of the Radium Beam Research as a medical research unit of the Medical Research Council. Arrangements are also being made whereby the Property Trust money held by the Royal College of Surgeons for the Radium Institute shall be used to provide a comparative test of the relative therapeutic values of radiation produced by a radium beam and that of a 200 KV deep therapy plant. The experiment has the approval of the Radiological Committee of the Medical Research Council and the British Empire Cancer Campaign. In order to ensure a strict comparison as possible the work will be undertaken by the staff of the Radium Beam Therapy Research. The secretary of the now completely amalgamated body, the Radium Institute and Mount Vernon Hospital, is Mr. F. A. Garner.

### THE NARCOTIC DRUG TRAFFIC IN EGYPT

Russell Pasha, in his report of the work of the Egyptian Narcotics Bureau for 1937, records the progress which has been effected during the last decade in combating the illicit traffic in dangerous drugs. He contends that

the wholesale manufacture in Europe of drugs for the illicit market has ceased. Moreover, by restricting supply he has raised the prices of narcotics. Whereas in 1929 the wholesale price of illicit heroin in Egypt was ££60 the kilo, it is now in the neighbourhood of ££600 the kilo, and is entirely out of the reach of the fellahin. By the abolition of the capitulations foreign traffickers are now dealt with in the Egyptian courts without the intervention of foreign consuls; severe penalties are inflicted, up to imprisonment for five years and a fine of ££1,000. Russell Pasha warns the Egyptian Government against the return of wealthy traffickers who have been deported and urges the authorities to be adamant in refusing re-entry of these incorrigible foreigners who so nearly brought Egypt to its death.

The world's supply of contraband heroin still passes from the Far East through the Suez Canal to Europe and America, and though some will inevitably drop off at Suez and during the canal transit, the local situation is now well in hand. A clean capture of 36 kilos of opium and 2.75 kilos of hashish in course of transit from Palestine to Kantara is reported. In all 552 kilos of opium were seized during 1937, chiefly in 'Sinai, Suez, and Kantara. In regard to the treatment of narcotic addiction, experience in Egypt confirms the conclusions arrived at in the United States—namely, 'that there is no medicine known which will cure one addicted to the use of narcotic drugs without his consent or against his will. So-called cures are

held to be "not cures at all, but merely temporary de-narcotization of basically unstable and abnormal persons" Addiction in Egypt while decreasing in the cities, is increasing in the provinces, especially in those adjacent to the Suez Canal and the Palestine frontier, while hashish is the narcotic most frequently resorted to During last year 2,866 persons were accused of possession, trafficking cultivation, or addiction, and 1 802 were committed and sentenced to imprisonment, accompanied in most cases with fines Illicit cultivation of the opium poppy has been increasing in Upper Egypt but the Narcotics Bureau, by means of aeroplane patrols, has located and photographed several hundred acres of flowering opium poppy and secured conviction of the cultivators Attention is again directed to "the harmful drinking of a black brew of adulterated tea" The International Tea Bureau, however, is, by means of travelling motor caravans, teaching the villagers how proper tea should be made Russell Pasha urges the reduction of the heavy import duties on tea and tobacco, by encouraging the use of "these harmless creature comforts" he hopes that resort to dangerous narcotic drugs might thus be lessened

#### EFFECTS OF ANOXAEMIA IN ANGINAL SUBJECTS

It is generally accepted that anginal pain is brought about by ischaemia of the myocardium, but it is not known whether this acts entirely or partly by reducing the supply of oxygen or in some other way It has been suggested that the pain is caused by certain products of metabolism which accumulate when the flow of blood through an active muscle is deficient, and according to this view lack of oxygen is not the most important factor—but according to R L Levy and A L Barach<sup>1</sup> it is They devised an apparatus for inducing oxygen want without the necessity for rebreathing, and observed the effect of inhaling air with an oxygen concentration of 12 per cent on thirty-seven patients with heart disease nearly all of whom had angina, and on eleven with normal hearts In the experiments the saturation of arterial oxygen fell to an average level of 75 per cent and the pulse rate, respiratory rate, and systolic blood pressure were usually increased The effect on venous pressure was variable, but the circulation time was always decreased in the patients with cardiac disease except in two with aortic stenosis In the normal group the circulation time was only slightly decreased The electrocardiograms of the patients with heart disease altered in form, the T wave becoming flattened or inverted and the RS-T segment deviating, as is sometimes observed in spontaneous angina Pain developed during the test in about half the patients with angina but in none of those with normal hearts It was found however that there was no uniformity in the conditions which gave rise to pain a patient might have pain in one test but not in another and it was impossible to correlate its onset with the changes in pulse rate blood pressure venous pressure circulation

time, or saturation of arterial oxygen, except in the two cases of aortic stenosis, in which a sharp and prompt response always took place under given conditions Levy and Barach reconcile the variable results of their experiments with their belief in the importance of anoxaemia in the production of cardiac pain on the hypothesis that there are various mechanisms, particularly quickening of the rate of circulation, which can compensate for the reduced saturation of arterial oxygen The constancy with which pain could be produced in aortic stenosis is thus correlated with the unchanging rate of circulation in these cases The test can be regarded neither as reliable nor as safe for the diagnosis of angina or coronary insufficiency, as in this series severe symptoms occurred in two instances, but the results show at least that anoxaemia is one important factor in the causation of cardiac pain

#### THE DOCTORS' COOKERY BOOK

The continued concern of the medical profession with the more practical aspects of nutrition is reflected in the publication to-day of *The Doctors' Cookery Book* (British Medical Association, 4d) This is a grand child of the 1933 report of the B M A Nutrition Committee, and the direct successor of *Family Meals and Catering* The committee's original task was "to determine the minimum weekly expenditure on food stuffs which must be incurred by families of varying size if health and working capacity are to be maintained, and to construct specimen diets" Dietary tables were drawn up, applicable to families of different sizes, and with the help of medical officers of health these diets were priced Useful as was this report, the chain from physiological laboratory to market and kitchen remained incomplete With suitable expert assistance the committee therefore proceeded, in 1934, to the preparation of *Family Meals and Catering* The purpose of this latter booklet was to translate the most widely useful of the above diets (that for a man, wife, and three children aged 6-8, 10-12 and 12-14 years) into the practical form of menus, recipes, and shopping lists for three weeks It received a ready welcome from local authorities, and a sale of 120 000 copies was quickly achieved Gratifying as was this result, the circulation of the booklet was none the less small in relation to the number of households which according to Sir John Orr, must be living on or below the nutritional borderline Accordingly an attempt has now been made in *The Doctors' Cookery Book*, to make a more direct appeal to the working class housewife The new booklet has an attractive cover, and is printed in convenient size for the kitchen The text has been rewritten and simplified and the complete dietary carefully re-examined in the light of the expert report which is printed at page 1326 of this issue Each of the dishes comprised in the three weeks menus has been specially made up and photographed and each day's menus now face a full page of illustrations In addition the price has been reduced and every effort to secure publicity for the booklet is being made

<sup>1</sup> *Am. Heart J.* 1935 15, 187

Copies are obtainable from any bookseller or news agent as well as from all W. H. Smith's bookstalls and co-operative societies. The help of medical practitioners in making the publication known will be welcomed. All inquiries should be addressed to the Secretary, British Medical Association, Tavistock Square, London, W.C.1.

### THE NOCHT Festschrift

Under the title *Festschrift Bernard Nocht* a volume has been published containing a foreword by Professor Muhlens and some 116 papers on various subjects relating to tropical medicine contributed by the friends and pupils of Professor Bernard Nocht in commemoration of his eightieth birthday. Professor Nocht, the founder and first director of the Institut für Schiffs- und Tropenhygiene at Hamburg, has a wide international reputation in tropical medicine. He is known especially for his researches on beriberi, malaria and blackwater fever, but his name is perhaps most familiar to many as the first to introduce under the name of Nocht's modification the now universally used Romanowsky method of staining malaria parasites. At the time of the great cholera epidemic at Hamburg in 1892 Nocht was chosen to direct measures against this disease and he later became increasingly concerned with the organization at Hamburg for the investigation and treatment of tropical disease in connexion with shipping and the German colonies. These activities led to the founding of the Hamburg Institute of Tropical Medicine and Nocht's appointment as its director, the post he still holds. The numerous papers in the *Festschrift* arranged alphabetically according to authors cover a wide field. Especially interesting in view of the occasion for its publication is the short account by Dr Carmichael Low of the foundation of the different schools of tropical medicine which now form such important centres of medical research and teaching in this country and in Germany. The Liverpool School was officially opened in April 1899 and the London School in October of the same year. This was followed by the opening in 1900 of the Hamburg Institute, an account of which with its threefold functions of research, teaching and provision of hospital treatment for tropical diseases is given by Professor Sonnenschein. Since its foundation 2,661 postgraduate students have attended courses in tropical medicine and associated with its many activities are such well known names as Nocht, Fülleborn, Giemsa, Schaudinn, Muhlens, Ruge, Schilling, Martini and others. Among contributions of a more directly scientific character are a number of papers dealing with malaria and related subjects. Notable among these are papers on various aspects of recent research upon the fate of the sporozoite and the significance of the endothelial stage in certain forms of bird malaria brought into prominence recently by the researches of Raffaele, James and Tate and others. In this connexion Brumpt records his results obtained in the treatment of *P. gallinaceum* in fowls with quinine, plasmoquine and atabrin. Administration during the

incubation period as with human malaria does not prevent the infection developing. But once parasites have appeared in the blood such infection is readily controlled. The same phenomenon is observed in blood inoculated as in mosquito infected birds and the author inclines to the view that the drug is not effective during the incubation period because the infecting organism has by then not sufficiently developed in numbers to bring about the degree of immunity which on this view is necessary to the effective action of the drug. In relation to blackwater fever an important contribution is made by Fairley who gives a very clear account of the conditions pertaining to intravascular haemolysis and the mode of formation and significance of the new blood pigment pseudo-metnaemoglobin discovered by him. In connexion with the same syndrome Malamos has studied the relation of liver damage brought about by antimony and by carbon tetrachloride to haemoglobinuria in monkeys infected with *P. knowlesi*. Haemoglobinuria did not occur as a result of such treatment and the author considers therefore that the haemoglobinuria occurring in this infection in monkeys is distinct from blackwater fever in man. An important paper is one by Weise describing a new test for determining plasmoquine quantitatively in the urine. This test, which depends upon the formation of an azo compound with *p*-arsanilic acid, appears to be much more delicate than that dependent upon the blue colour given in the chloroform test. We note that for quantitative purposes the test has been found particularly valuable. Of subjects other than malaria some half dozen papers relate to *Leishmania*, a description being given by Nattan Larnier of schizogonous metacyclic and pseudocystic forms of *L. donovani* whilst Napier discusses the method of testing drugs against kala-azar and records results obtained with a new antimonial drug (No. 561) which gives no local reaction injected intramuscularly and as regards effectiveness is in the same class with neostibosan. Other papers relate to a great variety of other subjects in tropical medicine impossible to specify in detail.

### SPREAD OF YELLOW FEVER IN AFRICA

In the annual report of the Department of Public Health Union of South Africa for the year ended June 30 1937 reference is made to the possibility of the spread of yellow fever from its endemic areas on the west coast to other parts of the continent and more especially to the Union itself. The vulnerability of the port of Durban Bay is pointed out, a locality where it is impossible to depend upon an entire absence of susceptible mosquitos at any time of the year. The report forecasts that, if ever yellow fever were introduced into Durban it would probably be a comparatively simple matter with the efficient corporation health department available to eliminate the disease in the town itself. If however it once succeeded in penetrating the surrounding country, the difficulties involved in checking its spread would be almost insuperable. The Department stresses the necessity for making the health

of South Africa one hundred per cent safe, and maintains that it is not enough to rely on the efforts of neighbouring countries. With this end in view extensive experiments in methods of fumigation of aircraft were carried out under the auspices of the Department, and improved apparatus was successfully devised. Proposals have been submitted to make every aeroplane self-contained in the matter of defence against insects. With regard to the seaplane service the procedure on arrival at Durban is to fumigate the flying boat and its contents at the moorings. Passengers then proceed to the quarantine float, moored close by in a position safe from shore mosquitos. Here the health, immigration, and Customs formalities are carried out. The quarantine float functions both as an examining office and as a small isolation hospital unit. Should it be necessary to detain passengers, it is a simple matter to have any special hospital equipment required brought from the shore, and by towing the float to a selected berth in the bay away from the air base and from ships' moorings, to secure complete isolation from man, mosquitos, and shipping.

### BRITISH HOSPITALS IN CHINA

We publish to-day at page 1339 an influentially signed letter addressed to members of the medical profession on behalf of the Lord Mayor's Fund for the Relief of Distress in China. This plea for sympathy and active co-operation in the relief of suffering is reinforced by the honorary secretary and treasurer of the Fund, Dr H Gordon Thompson. Goods in kind, or money to buy drugs, dressings, or instruments will be welcome. Without an ample supply of medical stores the hospital work for wounded, both civilian and military, cannot go on. Everywhere people are asking "What can we do about China?" There is one thing that can be done and is being done, for the Chinese in their hour of desperate need. Whatever the outcome of the war, China will not forget that British men and women did their best to alleviate her sufferings at the risk, and even at the cost, of their lives. Our medical colleagues must be supported in this gallant work.

### DAWSON WILLIAMS MEMORIAL

The Dawson Williams Memorial Fund was established by voluntary subscription in 1928 in commemoration of the late Editor of the *British Medical Journal*. Its object is the award of a prize every two years, or at longer intervals in recognition of work done in connexion with paediatrics. The Fund is administered by the following Trustees: the Presidents (for the time being) of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, and the Section for Disease in Children of the Royal Society of Medicine and the Editor of the *British Medical Journal*. The fifth award of the prize (which consists of a certificate and a cheque for 50 guineas) is due to be made in 1938, and the Trustees have chosen

as the recipient Professor Leonard Parsons M.D., F.R.C.P., of Birmingham, for his researches into diseases of children. With the consent of the Council of the British Medical Association the prize will be presented by the President of the Association on the occasion of his Presidential Address at Plymouth on Tuesday, July 19. Professor Parsons will give a lecture on the subject of the prize entitled "Some Nutritional Problems of Childhood" before the Section of Diseases of Children at the Plymouth Annual Meeting on Thursday, July 21.

### HORSLEY MEMORIAL LECTURE

The Victor Horsley Memorial Fund, which was raised in 1920 to commemorate the services of Sir Victor Horsley to Science and the Empire, is devoted to the giving of a lecture triennially in London. By invitation of the Trustees (the Presidents for the time being of the Royal Society, the Royal College of Surgeons of England, and the British Medical Association, the senior physician to the National Hospital for the Paralysed and Epileptic, Queen Square, the senior surgeon to University College Hospital and Mr Stanley G Robinson, son-in-law of Sir Victor Horsley) the sixth Victor Horsley Memorial Lecture will be delivered by Dr Gordon Holmes, F.R.S., physician to the National Hospital and to Charing Cross Hospital, on Tuesday July 12, at 5 p.m., in the lecture theatre of University College Hospital Medical School, Gower Street, W.C. The title of the lecture is "The Cerebral Integration of the Ocular Movements" and the chair will be taken by Sir Cuthbert Wallace, Bt, P.R.C.S. Admission is free on presentation of a visiting card, and tea will be served in the library of the Medical School at 4.30.

### BIRTHDAY HONOURS

The full list of medical honours conferred on June 9, the official day for celebrating His Majesty's birthday will be found at page 1329 this week. Knighthoods are to be conferred on four members of the profession. Mr William Girling Ball, surgeon and Dean of the Medical College St Bartholomew's Hospital, has done great work for Bart's, more particularly in securing the Charterhouse buildings for the College. Last year he was appointed Dean of the Faculty of Medicine of the University of London. Dr Henry Howarth Bashford, Chief Medical Officer, General Post Office is well known to the medical profession and the public as a writer of essays and stories. Dr William John Handfield Haskett, a past chairman of the South Middlesex Division of the British Medical Association, receives his honour for political and public services in the Spelthorne Division of Middlesex. Mr Robert Blakeway Wade is President of the Medical Board, State of New South Wales and was elected President of the Royal Australasian College of Surgeons in 1935. He has been a leader in the work of the New South Wales Branch of the British Medical Association of which he was President twelve years ago, and holds many important positions in Sydney.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## QUINSY AND RETROPHARYNGEAL ABSCESS

BY

R. SCOTT STEVENSON, M.D., F.R.C.S.D.

The term quinsy had in the past a much less restricted application than it has to-day. To medical surgeons, cyanotic meant any kind of a sore throat—indeed what appears to have been diphtheria—and even Merrell Mackenzie (1880) used quinsy as a synonym for acute tonsillitis. To-day, however, we take it that a quinsy is a peritonsillar abscess—suppuration in the tissues of the soft palate outside the capsule of the tonsil. It does not originate in these tissues but results from infection of the crypts of the intratonsillar fossa. The fossa when it is often inaccurately named is confused with the superior tonsillar fossa or sinus above the tonsil and between the pillars of the fauces; it has been called by some authorities the tonsillar recess, superior tonsillar fossa or crypta magna and is situated in the upper pole of the tonsil going right down to the capsule (see Fig. 1). It becomes

FIG. 1—Diagram of tonsil. A intratonsillar fossa. B site of development of peritonsillar abscess.

infected usually after an acute tonsillitis though this may be transient and the infection may appear to be a primary one in the fossa itself. The mesial end of the fossa is blocked up by the process of inflammation. An abscess forms and bursts through the thin capsule of the tonsil at the deepest part of the fossa. It then spreads into the areolar space between the capsule and the superior constrictor muscle. Sometimes the abscess does not burst through the capsule and a true tonsillar abscess is formed but this is comparatively uncommon and the symptoms are much less severe than those of a peritonsillar abscess. A one-sided swelling of the tonsil should always be carefully examined and palpated: a tonsillar abscess has been known to be confused with a sarcoma and a mixed palatine tumour.

### Symptoms

The condition is most common in young adults and is relatively rare in children. The onset is gradual, though it has been preceded by acute tonsillitis. The temperature is rarely above 100° F. in an acute tonsillitis the temperature may go up to 103° F. or more. Pain increases progressively until it becomes almost unbearable. The patient feels extremely ill and unable to swallow, sometimes almost choking, with saliva dribbling from the mouth—a characteristic sign. The pain may radiate up to the ear and down to the neck, lateral movements of the head

make the pain worse and the patient may hardly be able to open his mouth for an examination of the throat.

He commonly has an anxious expression and his breathing may be interfered with. There is a lot of thick viscid secretion in the throat which the patient finds difficult in removing. One side only is affected as a rule. The soft palate and uvula as well as the pharyngeal mucous membrane are congested and swollen and the tonsil is pushed downwards and backwards. The glands of the affected side of the neck are enlarged and tender. Pus forms about the third or fourth day of the illness which lasts for about five to fourteen days when allowed to run its course. Actually it never should be allowed to run its course. The complications of this condition may be serious and even fatal but immediate relief follows evacuation of the pus. Many surgeons are inclined to wait until the abscess to be definitely formed but it is delayed and not a man to open a quinsy early rather than late even if only blood and not pus flows from the incision.

### Opening the Abscess

Opening the abscess is not always as easy as it may sound. A gag may have to be used to keep the patient's mouth open; the throat is very swollen and the tonsil is congested backwards. The classical site of the incision is a horizontal line drawn across the base of the uvula and a vertical line drawn along the anterior pillar of the fauces (see Fig. 2). If the abscess is a large

FIG. 2—Peritonsillar abscess. A site of classical incision.

one an incision made at this point will usually evacuate it but it is not uncommon to fail to open the abscess with this technique even after several attempts. In most cases this is due to failure to take into account the fact that the tonsil often extends forwards beneath the anterior pillar of the fauces so that the incision penetrates the substance of the tonsil itself. In my opinion it is much better to make the incision through the intratonsillar fossa where the abscess has originated and to do so with blunt sinus forceps rather than with a scalpel or bistoury or other sharp instrument.

### TECHNIQUE OF INCISION

The patient should be propped well up in bed, his head being steadied by an assistant. A good light is necessary and is best provided by a forehead light which leaves both the operator's hands free. (A very efficient one with a battery that can be put in the pocket can be bought for 7s. 6d.) The light from an electric torch in the hands of an inexperienced assistant is apt to be unsteady and misdirected. The patient if he can may suck a benzocaine lozenge for ten minutes before the incision is made or the throat may be sprayed with a small amount of 10 per cent cocaine hydrochloride solution but no local anaesthetic has much effect in quinsy.

The patient's tongue is depressed with a spatula held in the left hand. A pair of sinus forceps held in the right hand are pushed sharply backwards and upwards under the base of the uvula into the intratonsillar fossa if it can be seen or at least into the upper part of the posterior pillar of the fauces, for a distance of an inch or more until the pus is found (see Fig. 3). The sinus forceps are then opened widely to allow

FIG. 3.—Method of opening peritonsillar abscess through the intratonsillar fossa by means of sinus forceps.

of its evacuation. The forceps are quickly withdrawn the patient's head is bent well forwards to allow the pus to run out of his mouth and he is then given a warm mouth-wash of bicarbonate of soda solution, glycerin of thymol or the like.

#### Tonsillectomy

Sometimes it may be necessary to open a peritonsillar abscess more than once, and if the abscess fills again after a second incision it will be well to consider whether the tonsil should not be removed. There has been a good deal of controversy on this subject of recent years, though as a matter of fact the problem is by no means a new one. Chassaignac, as early as 1859, said that he would not hesitate to remove the tonsil in a case of "tonsil suppuration." It has been suggested by Canuyt and others (1933) that general anaesthesia for this purpose is dangerous on account of the possibility of subsequent pulmonary infection from pus aspirated into the lung, and also that the operation is dangerous because of the "fresh field opened up for infection."

Many American, French, German, and other authorities—along with a few in this country—have put their experience of tonsillectomy for peritonsillar abscess on record. With ordinary precautions there seems no reason to believe that pus is likely to be inhaled by the patient, or that the wound made by the tonsillectomy is liable to be any more dangerous than the usual incision made through the soft palate. However, in the vast majority of cases the question will not arise especially when the abscess is opened in the manner described above. I have personally removed the tonsil for peritonsillar abscess on six occasions only twice under local anaesthesia, 2 per cent novocain being injected after spraying with 10 per cent cocaine and four times under general anaesthesia. In each case the abscess had filled up again after it had been opened apparently thoroughly, on two or more occasions. In one instance the abscess was found to be situated at the lower and not the upper pole of the tonsil.

#### Complications

The complications of peritonsillar abscess, such as oedema of the glottis and haemorrhage, are rare but alarming. There is one type of abscess, fortunately atypical, in which the pus burrows laterally, bursts through the superior constrictor muscle and becomes localized in the pharyngo-maxillary space. Such an abscess is difficult of approach and the pus may burrow still further down-

wards and enter the mediastinum. The great vessels of the neck in such a case are close to the abscess cavity and thrombophlebitis may develop in them. In other cases the abscess may ulcerate one of the large arteries in the submaxillary region, and it has been necessary on occasion to ligate the external carotid artery. An abscess left to mature has been known to give rise to cavernous sinus thrombosis. Such complications, however, should not arise if the importance of early and thorough evacuation of the abscess is realized.

#### Retropharyngeal Abscess

Retropharyngeal abscess is of two types: the chronic, which is of tuberculous origin, usually secondary to tuberculous disease of the cervical vertebrae, and the acute, due to suppuration in the lymphatic glands (the glands of Gillette) situated behind the mucous membrane of the posterior pharyngeal wall. Though present in infancy, these glands gradually disappear as the child grows older, and are seldom present after the age of 2 years. They drain the nasopharynx and pharynx, and their efferent lymphatic vessels go to the upper group of deep cervical glands in the posterior triangle of the neck and beneath the sternomastoid muscle. There are two symmetrical pairs of glands, lying on each side of the vertebral column, so that when they become inflamed, from infection of the nose or throat, the process begins by being one-sided, but it gradually develops in the middle line because of the laxity of the submucous tissue in this region.

Acute retropharyngeal abscess is comparatively rare, but it has been said that probably no acute illness of childhood is more often overlooked. It occurs always in young children and should especially be kept in mind when an infant under the age of 12 months, after an ordinary cold with the usual symptoms of fever and nasal obstruction, shows signs of difficulty in swallowing and in breathing. Dysphagia accompanied by dyspnoea is very characteristic of retropharyngeal abscess. Usually there will be also the signs and symptoms associated with any serious illness in infants, such as high fever, often vomiting, and sometimes convulsions. The infant will try to feed, but chokes, coughs, and cannot drink its milk; it will then put its head back and cry. The dysphagia is caused by the mechanical obstruction due to the swollen pharynx and soon brings about a rapid loss of weight. Dyspnoea is usually noticed later and is also mechanical in origin, the progressive development of the abscess blocking the respiratory tract. The dyspnoea is sometimes spasmodic, and sometimes there is a change in the child's voice.

The condition is often mistaken for some other ailment, such as bronchitis, a foreign body in the larynx or lung, tonsillitis, peritonsillar abscess, oedema of the glottis, diphtheria, or even meningitis. The diagnosis is made by remembering that every sick child should always have its throat examined in a good light. The tongue should be held down by a spatula and the pharynx should be carefully palpated by the forefinger. In retropharyngeal abscess there is a red swelling of the back of the throat, sometimes rather hidden by the uvula, less often the swelling is lower down in the hypopharynx. It feels resistant and rather elastic to the touch; in the later stages fluctuation may be detected.

If the abscess is not opened the outlook is serious. Death may result from oedema of the glottis, asphyxia or heart failure from pressure on the vagus, and if the abscess bursts spontaneously a septic pneumonia will probably follow. Once the diagnosis is made the abscess should be opened, without waiting for fluctuation.

The infant is wrapped up in a blanket or a towel and laid flat on its back with a small sandbag or a rolled towel under its shoulders. Its limbs are held by its wrists and its knees are flexed. A spatula is usually all that is required to keep the tongue back and the child should not be moved. With the aid of a forehead light a pair of sinus forceps is plunged into the most prominent part of the swelling, i.e. the tip of the

FIG 4—Opening a retropharyngeal abscess with a pair of sinus forceps.

opened widely to allow the pus which may be profuse to amount to four out. The infant is at once lifted up by its legs, so that the pus cannot get down to the lungs. The drainage is usually satisfactory but convalescence is slow because the child is generally in a poor state of health before the abscess is opened.

If the abscess points towards the neck opening through an external incision may have to be considered but it should not be looked upon as the incision of choice as used to be the case, for the dangers of opening the abscess by way of the mouth were formerly exaggerated. With ordinary precautions lung complications should not follow the opening of a retropharyngeal abscess by the method described.

## VOLUNTARY HOSPITALS EMERGENCY BED SERVICE

In our issue of June 4 (p. 1221) we published a short account of the scheme and the objects behind it. The service will come into operation on Tuesday, June 21 at 8 a.m. and it is now possible to give full details so that practitioners may know how it is worked and how to make use of it. The service will be open from 8 a.m. to 10 p.m. seven days a week in the early stages and will subsequently be extended to cover the twenty-four hours.

Since it is not possible to estimate accurately the number of calls which will be received the letters informing doctors that the service is at their disposal and giving the telephone number will be sent out in instalments in alphabetical order so that if necessary the issue can be stopped if it is found that more calls are coming in than the staff can deal with. The issue will be resumed so soon as the staff has been sufficiently increased. In actual fact a larger staff has been appointed than is expected to be necessary to work the day service so that it is not likely that the sending out of letters will be delayed.

#### Procedure for the Doctor

When a doctor desires to obtain admission to hospital for an emergency or acute case he can ring up the service whereupon he will be asked to give his name and telephone number, the patient's name, address, sex, and age and his diagnosis. He should then say to which hospital he wishes to have the patient admitted. With this informa-

tion the operator will be able to inform him whether or not a suitable bed has been reported free at that hospital. If no bed is free there then another hospital can be considered forthwith. When a bed is reported free the operator will obtain confirmation from the hospital in question for it may have been filled since the last report. On receiving confirmation she will book the bed and inform the doctor. There are two points in the course of this process at which it is suggested that the doctor could help the operator and himself: first, by saving at the end of his diagnosis whether it is a medical, surgical, ophthalmic, otolaryngological, orthopaedic or other case; and secondly by giving a choice of hospitals so that if the bed reported free at one has been filled she can ring the other forthwith without further reference to him.

#### How Hospital Accommodation is Indicated

It is perhaps well to explain how the list of free beds of all the hospitals is to be kept before the operators. This will be done by means of a large indicator board on which will be written the names of the hundred co-operating hospitals, against these names tickets will be run, representing the free beds. The tickets will be made in different pairs to indicate the sex—for example all male tickets will be square, the female ones round and the children's triangular. The types of bed—whether medical, surgical, etc.—will be indicated by colours. Thus once the indication of the case is clear the operator will be able to find accommodation almost at a glance.

The operators have not had medical training but a number of them have worked in hospitals or been doctors, secretaries, and nurses have acquired a certain familiarity with medical terms. It is expected therefore that they will all soon pick these up. At first however and always in the case of obscure or rare cases it will be a great help if doctors provide a general classification as well as the diagnosis.

As regards the beds indicated as free it would obviously be ideal if hospitals were to report to the service every time a case was admitted or discharged thus enabling an accurate up to the minute record to be always available. But this would involve such an expenditure of time and money in telephone calls that it would defeat the object of the service. So a compromise has been struck and to begin with the record will be obtained twice daily at times that have been arranged to suit the individual hospitals. Generally speaking the first record will be taken between 8 and 10.30 a.m. and the second between 4 and 7 p.m. Only on practical experience can it be decided whether more frequent records are necessary or desirable.

#### The Service as a Working Experiment

It will be gathered from the foregoing that at first the whole service must be partly in the nature of a working experiment. No service on a comparable scale exists anywhere else so that the details have had to be worked out to suit the conditions and all are open to revision in the light of experience. There is no reason why the scheme should not run smoothly after a fairly short period provided always that the doctors and hospitals alike give it their friendly support.

In conclusion it is perhaps worth while pointing out that for any given case there are probably some twenty-five hospitals to which it could reasonably be sent and a survey of all these can be made in a few minutes. For instance a gynaecological patient in North London could go either to one of the North London general hospitals or to one of the Central London general hospitals or the doctor might prefer to send her to a hospital specializing in diseases of women. It thus seems unlikely that in normal times it will not be possible to find a bed in any of the hospitals in these three groups. It is to be hoped therefore that one call on the bed service will prove an attainable ideal.

## THE DOCTORS' COOKERY BOOK, 1938

AN ASSESSMENT OF THE NUTRITIONAL  
VALUE OF THE DIETS

Recent progress in the assessment of the vitamin and mineral content of foodstuffs, and the acceptance by leading authorities on nutrition of certain standards for individual daily intake of these important constituents of protective foods made it desirable to re-examine the nutritional value of the family dietary (No 16 of the B M A Nutrition Report of 1933) which was used as the basis in the booklet entitled *Family Meals and Catering* before deciding on the publication of a new edition.

In response to a request from the British Medical Association the Ministry of Health indicated that information as to accepted standards of individual requirements for minerals and vitamins, and of values for the content of various foodstuffs in respect of these constituents, could be found in the publications listed at the end of this report. The present assessment of the adequacy or otherwise of the mineral and vitamin content of the three-weeks dietaries for a family of man, wife, and three children aged 6 to 14 years was based on information contained in those publications and can therefore be taken as an assessment of the nutritional value of the diets in the light of most recent scientific knowledge and opinion.

## Minerals

## (a) STANDARDS

Sherman (1937) publishes a table of the mineral and vitamin contents of a diet 'to furnish not only the minimum requirements of the body but an ample margin of safety as well'. The original table is from Stebeling (1933), this table is also used by Orr as his standard in *Food, Health and Income* (Table I).

TABLE I—Quantities of Nutrients for Individuals per Day  
Minimum Requirements with Ample Margin of  
Safety (Stebeling 1933, Sherman 1937)

Individuals by Age, Sex and Activity Groups	Energy Value (Calories)	Dietary Allowance in			
		Protein (Grammes)	Calcium (Grammes)	Phos- phorus (Grammes)	Iron (Grammes)
Child under 4 years	1 200	45	1 00	1 00	0 006 0 009
Boy 4-6 years	1 500	55	1 00	1 00	0 008 0 011
Boy 7-8 years	2 100	65	1 00	1 00	0 011 0 015
Boy 9-10 years	2 400	75	1 00	1 20	0 012 0 015
Child 11-13 years					
Moderately active woman					
Boy 11-12 years					
Girl over 13 years	2 500	75	1 00	1 20	0 013 0 015
Very active woman					
Active boy 13-15 years	3 000	75	0 88	1 32	0 015
Active boy over 15 years	3 000-4 000	75	0 88	1 32	0 015
Moderately ac- tive man	3 000	67	0 68	1 32	0 015
Very active man	4 500	67	0 68	1 32	0 015

On examining the table it will be noticed that there is some apparent discrepancy in the standard for calcium: the moderately active woman having a larger allowance of calcium than the very active woman, but a smaller allowance of phosphorus. On inquiry into this point it was ascertained that the diet from which this table was drawn up was not intended to set a standard but to indicate a possible adequate diet at a minimum cost and that primarily the moderately active woman was classed with the boy 11 to 12 (or girl over 13) on the basis of calorie requirement. Attention was also drawn to the fact that 0 88 or 1 00 gramme of calcium is above the present suggested standard of 0 75 gramme daily for an adult female.

On the basis of this table with the new figure of 0 75 as a minimum Ca the B M A family of diet No 16 would have

the following calorie, protein, and mineral requirements (Table II)

TABLE II

	Calories	Grammes of			
		Protein	Calcium	Phos- phorus	Iron
Man	3 000 (up to 4 500)	67	0 68	1 32	0 015
Wife	2 500 (up to 3 000)	75	0 75 (up to 1 00)	1 20 (1 32)	0 014 (0 015)
Child 6-8	1 500	55	1 00	1 00	0 010
" 10-12	2 500	75	1 00	1 10	0 012
12-14	2 500	75	1 00	1 20	0 014
Daily total	12 000 (up to 14 000)	347	4 43 (up to 4 68)	5 82 (up to 5 94)	0 065 (up to 0 066)
Weekly total	84 000 (up to 98 000)	2 429	31 01 (up to 32 76)	40 74 (up to 41 58)	0 455 (up to 0 462)

As the sex of the children in the B M A family was not stated and as in Stebeling's table boys received a higher allowance of some constituents than girls of the same age, the difference has been split to give an average—that is, child 10 to 12, 1 10 grammes P. The *Family Meals and Catering* variations being of weekly rations, the Stebeling daily allowances have been brought up to weekly ones, to admit of direct comparison.

## (b) CALCULATION OF MINERALS (CALCIUM, PHOSPHORUS AND IRON) IN THE B M A VARIATIONS OF DIET NO 16

The publications quoted by the Ministry of Health give a wide choice for the assessment of the mineral content of foodstuffs, and include all those items listed in *Family Meals and Catering*. The data of mineral content from these sources, together with the appropriate McCance factor to allow for losses through cooking, waste, etc., of meat or fish, fruit and vegetables, have been used in the present assessment of minerals in the three-weeks variations of diet No 16. Hence the resulting mineral content for each week will be practically the net total. The three-weeks variations, when worked out from the analyses chosen, give the following results (Table III).

TABLE III

	Calories	Grammes of			
		Protein	Calcium	Phosphorus	Iron
Week I	98 874	3 003	30 07975	47 77567	0 50398
II	99 377	2 836	28 72247	46 25129	0 48772
III	98 593	2 753	25 18224	42 77382	0 52066
Average weekly	296 844 98 948	8 592 2 864	83 98446 27 99482	136 80078 45 60026	1 51236 0 50412

On comparing these results with the weekly allowances of Table II it will be seen that the average content of the three-weeks diet is well up to the Stebeling diet, which was calculated to 'furnish an ample margin of safety' in everything but the calcium content. Family No 16 contains three children of school age. If these three children drink a third of a pint of milk each at school (five days weekly, at 1<sup>st</sup> d per day = 7<sup>th</sup> d), and the food value of the five pints of milk is added to the weekly average content of the diet, while the monetary equivalent in amount of bread is deducted (4<sup>th</sup> lb of bread at 3<sup>rd</sup> d per 2 lb (cost in 1933) = 7<sup>th</sup> d), the result is as follows:

	Calories	Grammes of			
		Protein	Calcium	Phosphorus	Iron
Less Bread	-4 407	-132 0	-0 576	-1 3700	-0 01512
More Milk	+1 890	+ 93 5	+ 3 400	+ 2 6400	+ 0 00612
	-2 517	- 45 5	+2 824	+0 7700	0 00000

These figures added to or deducted from the averages of Table III will not make all allowances for the amount of the other constituents but will bring the calcium to the required level

Calcium	Calcium		
	Protein	Calcium	Iron
45	104	2505	50
100	100	2514	50
150	218	3000	50

### Vitamins

#### (a) STANDARDS

Only very tentative suggestions for the assessment of standards in vitamins or of the quantity of vitamin foods (evaluated as units) can be had at the present moment. Strehling (1933) gives the following quantities of vitamin A and vitamin C yielded by the adequate diet at minimum cost (Table IV).

TABLE IV—Quantities of Nutrients for Individuals to furnish not only the Minimum Requirements of the Body but an Ample Margin of Safety (Strehling 1933, Sherman 1937)

Individuals by Age Sex and Activity Groups	Vitamin A (S. Sherman Units)	Vitamin C (S. Sherman Units)
Child under 4 years	100	5
Boy 4-6 girl 4-7 years	300	5
" 7-8 " 8-10	300	5
" 9-10 " 11-13	500	5
Very active woman boy 11-12 years	4000	65
Girl over 13 years	4000	100
Very active woman active boy 13-15 years	4000	100
Active boy over 16 years	4000	100
Very active man	4000	100
Very active man	4000	100

Daniel and Munsell (1937) on analysis of diets providing at least the minimum daily requirements for protein calcium phosphorus iron and calories have also estimated the vitamins yielded by such diets and the Bureau of Home Economics is using the results of this calculation as a very tentative standard for the various vitamins (Table V).

TABLE V

	Vitamin A	Vitamin B <sub>1</sub>	Vitamin C	Vitamin D	Vitamin B <sub>2</sub>
Per 1000 kcal/day	6000 Sherman Units	600 Sherman Units	150 Sherman Units	—	600 Sherman Units

For vitamin D they do not attempt to fix a standard

#### (b) CALCULATIONS OF VITAMINS IN THE B.M.A. VARIATIONS OF DIET NO. 16

From tables given by Daniel and Munsell (1937) it has been possible to make a fairly accurate estimation in Sherman units for vitamins A, B<sub>1</sub>, C and B<sub>2</sub> and in international units for vitamin D. In the case of various meats and eggs the vitamins in Daniel and Munsell's tables are estimated separately for lean and fat white and yolk. Where this is the case estimations for the vitamins yielded have been adjusted to the proportions of fat and lean etc. given by Plummer (1921) for the foodstuffs concerned. In the menu for Week III 1 lb rabbit is used. It has not been possible to trace any analyses of vitamins

in rabbit otherwise the lists are complete. In the case of B the vitamin content of a few foodstuffs is given in international units only and as the conversion figure into Sherman units is not standardized no attempt has been made to convert such units. Vitamin B<sub>2</sub> will therefore be present in the various foodstuffs in not smaller quantities than has been stated is the result of the calculations. But it must be emphasized that such calculations may not be accurate and these are however all that is at present available from published data.

From the Strehling table the following requirements for vitamins A, B<sub>1</sub> (daily man value 2891) in vitamins A and C can be constructed (Table VI).

TABLE VI

	Vitamin A (S. Sherman Units)	Vitamin C (S. Sherman Units)
I	4000	100
W	4000	95
C	500	5
" 1-2	500	5
" 3-4	500	5
" 5-6	500	5
" 7-8	500	5
" 9-10	500	5
" 11-12	500	5
" 13-14	500	5
" 15-16	500	5
" 17-18	500	5
" 19-20	500	5
" 21-22	500	5
" 23-24	500	5
" 25-26	500	5
" 27-28	500	5
" 29-30	500	5
" 31-32	500	5
" 33-34	500	5
" 35-36	500	5
" 37-38	500	5
" 39-40	500	5
" 41-42	500	5
" 43-44	500	5
" 45-46	500	5
" 47-48	500	5
" 49-50	500	5
" 51-52	500	5
" 53-54	500	5
" 55-56	500	5
" 57-58	500	5
" 59-60	500	5
" 61-62	500	5
" 63-64	500	5
" 65-66	500	5
" 67-68	500	5
" 69-70	500	5
" 71-72	500	5
" 73-74	500	5
" 75-76	500	5
" 77-78	500	5
" 79-80	500	5
" 81-82	500	5
" 83-84	500	5
" 85-86	500	5
" 87-88	500	5
" 89-90	500	5
" 91-92	500	5
" 93-94	500	5
" 95-96	500	5
" 97-98	500	5
" 99-100	500	5

The actual result of the calculations in the three weeks' period is shown in Table VII.

TABLE VII

	Vitamin A (S. Sherman Units)	Vitamin B <sub>1</sub> (S. Sherman Units)	Vitamin C (S. Sherman Units)	Vitamin D (S. Sherman Units)	Vitamin B <sub>2</sub> (S. Sherman Units)
Week I	1000	70	10	—	10
Week II	1000	70	10	—	10
Week III	1000	70	10	—	10
Average weekly	1000	70	10	—	10
Average daily	1000	70	10	—	10
Average per 1000 kcal	1000	70	10	—	10

Rabbit not included.  
† Vitamin B<sub>2</sub> not included.

The weekly figure is to be compared with the weekly total of Table VI. The daily per man value figure is to be compared with the figures of Table V. According to the Strehling standard vitamin C is low but according to Daniel and Munsell requirements in all vitamins are well covered without the readjustment proposed between bread and milk in the section on minerals which would raise the amount of vitamin A by over 4600 units weekly.

### Costs

Questionnaires were sent out to medical officers of health of various urban and rural districts in England and Wales including those who co-operated in the original investigation into costs in 1933. The questionnaires included all the foodstuffs listed in the three weeks' menus and it was asked that maximum medium and minimum prices of shops or markets in working class districts should be collected at the end of January or beginning of February on a Friday and Saturday. Full replies were received from the medical officers of health of seventeen widely distributed districts. In an average case a price appeared very different from national generally inquiry was made again and the statement was thus checked. From some

centres more than one questionnaire was filled up to represent different shopping districts in the city or county. When this was done the average cost (both maximum and minimum) of each article was worked out for that city or county so that each district might be represented once only in the total. Thus though thirty-five completed questionnaires were returned, the districts represented number seventeen. As so many centres were unable to furnish a medium price, only the maximum and minimum prices were finally averaged out for each article listed. The cost of the articles in the quantity stated in the shopping list for each week was then worked out on the two scales, correct to the nearest farthing. The cost on the two scales is as follows

TABLE VIII

	Cost in Pence	
	Minimum	Maximum
Week I	310 00	424 25
II	330 25	445 75
III	340 00	455 75
	980 25	1 325 75
Stores I	0 50	0 50
II	3 75	3 75
III	—	—
Total for 3 weeks	984 50	1 330 00
Average per week	328 1667	443 333
	27s 4½d	36s 11½d

The minimum price of 27s 4½d may be compared with the figure 22s 6½d (cost in 1933), the percentage increase being 21.3. The mean of the two prices (27s 4½d, 36s 11½d) would be 32s 1½d. It must be remembered that either scale of figures must be liable to considerable variation. The variation may be due to local, seasonal, or other factors.

### General Conclusions

The object of the present investigation was to assess the three-weeks variations of diet No. 16 in the light of present knowledge.

In regard to energy value, proteins, fats, and carbohydrates the diets conform to accepted standards. Of the minerals the requirements in phosphorus and iron are amply covered in each week but having regard to the fact that the family includes three children the calcium content might be increased as recommended in the original foreword to *Family Meals and Catering*—that is, that children of school age should take advantage of the school milk service. Calculations show that if this is done the requirement for calcium for growth is adequately met according to present opinion.

In regard to the vitamins it appears that the only deficiency is in respect of vitamin C, and this only according to one scale of adequacy (Stiebeling) and not to another (Daniel and Munsell). It may be thought desirable to increase the vitamin C content by purchasing according to season more citrus fruits, tomatoes, or green vegetables, and balancing their increased cost by an appropriate reduction in the money spent on meat. This would seem a reasonable modification in a family of this composition. It may be pointed out that in a family of the same man-value made up entirely of adults such modifications would not be necessary.

The present cost of the diets purchased at the minimum prices amounts to 27s 4½d, as against 22s 6½d in June 1933. This figure is 21.3 per cent. above that of the cost at 1933 prices.

### INTERNATIONAL HOSPITAL ASSOCIATION

The meeting of the Council of Management of the International Hospital Association has been held recently in Frankfurt-on-Main, when eleven countries were represented—namely, Canada, Czechoslovakia, Belgium, Eire, Germany, Great Britain, Holland, Hungary, Italy, Switzerland, and the United States of America.

Dr. Rene Sand occupied the chair, and his knowledge of German, French, and English made for smooth working. Dr. von Deschanden was thanked in his absence for his fine services to the association, and was elected as honorary president. Dr. W. Alter, to whom no one has given more needed help, was secured in his office of honorary secretary, and Miss R. M. Murray as executive secretary. Mr. E. Hirsch was appointed honorary treasurer. Much appreciation was evinced in the quarterly publication of the association named *Nosokomion* of which Dr. Alter is the able editor. Dr. Malcolm T. MacEachern, associate director of the American College of Surgeons, Chicago, was elected president and will preside at the congress of the association to be held next year in Toronto, Canada, from September 19 to 23, 1939. It is hoped that there will be a large contingent from Great Britain and Eire, as well as from Continental countries as the congress will be followed immediately by the Convention of the American Hospital Association.

The congress in 1941 will take place in Berlin, under the presidency of Dr. R. Zeitler of that city. Mr. W. McAdam Eccles M.S., F.R.C.S., brought a unanimous invitation from the United Kingdom Council of the I.H.A. to hold the congress of 1943 in Great Britain, and this was accepted with acclamation. There are forty study committees at work and their reports and resolutions will be presented to the congress in Toronto.

The International Hospital Association is increasing its number of national and individual members and thus growing in influence the world over. Anyone interested is invited to communicate with the joint honorary secretaries, International Hospital Association, 12, Grosvenor Crescent, London, S.W.1.

F. Blumenthal and W. L. Sherman (*Amer J Syph Gon* March 1938) discuss the cutaneous manifestations of gonorrhea. The metastatic manifestations include erythema, urticaria, erythema nodosum-like lesions, purpura, bullae, and hyperkeratoses, the last being associated with conjunctivitis and arthritis. The skin affection is at the extremities, the arthritis multiple and accompanied by only slight pain and not usually followed by ankylosis. A case is reported in which joint pains and penile dyskeratosis developed and disappeared with the exacerbations and remissions of a gonococcal prostatitis. The skin lesions differed from psoriasis in the presence of plasma cells, the arthritis was not associated with bony changes, and it is suggested that the skin and joint conditions were allergic manifestations due to the breakdown of gonorrhoeal metastases. Gonococci are rarely found in the lesions but there is always a positive blood complement fixation test.

## THE BIRTHDAY HONOURS

The Honours List issued on the occasion of the celebration of His Majesty's birthday included the names of the following members of the medical profession:

*Ambulance*

WILLIAM GIRLING BALL FRCS Surgeon to the Medical College St Bartholomew's Hospital  
HENRY HOWARTH BASHFORD MD MRCS C. M. S. Chief Officer General Post Office  
WILLIAM JOHN HANDFIELD HASSELL MRCS L.R.C.P. For political and public services in the Sudan and the Middle East  
ROBERT BLAKEWAY WADE MD FRACS F.R.C.S. (Ed.) the Medical Board State of New South Wales

*CB (Military Division)*

Major General GEORGE ALFRED DUNCA HON. (late R.A.M.C.) Honorary Physician to the King  
Director of Medical Service Western Command

*CMG*

Colonel GEORGE WYKHAM HILTON CBE DSO F.R.C.S. Medical Service Director of Medical Services

## SCIENTIFIC TREATMENT OF DELINQUENCY

The Institute for the Scientific Treatment of Delinquency held its general meeting at the British Industries Exhibition on May 26. Mr NORMAN BIRKETT K.C. President of the Institute said that he thought that the Institute had recently suffered from its name; it probably had not made the scope of the work but it only appeared proper to the initiated. The moment the psychology of crime was mentioned in this country a strong reaction was aroused in the minds of ordinary people. The English habit of mind had been more and more concerned with the need for a scientific approach to the cause and prevention of crime and the treatment of offenders. The English habit of mind had been to treat the causes of crime in a rather haphazard way. It was high time that the problem was dealt with scientifically. One of the most valuable activities of the Institute was the work it did in conjunction with magistrates' courts and probation officers.

Dr DE. IS CARROLL agreed that the name of the Institute was absurd. No treatment was strictly scientific in psychology or in medicine. The Institute would however stick to its name shortened for general use to ISTD. The relations of the Institute with the Home Office were closer than they had ever been. Some types of criminals were theoretically curable but psychologists did not yet know how to cure them. The clinic needed one or two half-time research workers for on the clinical side the best men were in private practice. One great difficulty about research in this kind of work was the storage of the inevitable bulky records. The study of delinquency on psychological lines had now reached a stage at which it could put forward suggestions as to definite lines of treatment.

The annual report showed a steady increase in the work although dealing with the 167 new cases strained the Institute's resources. The waiting list had been satisfactorily reduced by the appointment of a medical registrar and the assistance of a skilled social worker had been invaluable in finding and supervising accommodation for patients requiring inpatient conditions. Early in the year the Institute was asked to co-operate with the British Paramount News in a news reel on Shoplifting. In January the Institute was officially recognized by the Child Guidance Council as a child guidance clinic.

## Week-end Course

A week-end course of lectures for doctors on the causes and treatment of delinquency was held on May 28 and 29. Mr T. H. MARSHALL reader in sociology in the University of London spoke on the sociological aspect and dealt with the social causes of delinquency, the idea of responsibility and the social functions of punishment. Dr C. J. C. EARL opened a group discussion on Intelligence—

subnormal and supernormal—as a factor in delinquency.” He pointed out that the relation of intelligence to delinquency was indirect, and the intellectual factor had always to be considered in relation to the personality as a whole. Subnormal intelligence itself was a rare cause of crime. Dr J. D. W. PEARCE gave two lectures on the psychopathology of delinquency, showing how delinquency was a reaction to negative feelings engendered by the frustration of fundamental urges and how the delinquent gained compensatory satisfactions and escape from difficulty, usually without being aware of what he was doing. He also dealt with delinquency as a symptom of various psychoneuroses, psychoses and metabolic disorders. On the Sunday Dr DENIS CARROLL lectured on the medical treatment of delinquents. A general discussion took place on the topics raised in all the lectures.

### PREGNANCY AND PARTURITION AFTER AMPUTATION OF THE CERVIX

A meeting of the North of England Obstetrical and Gynaecological Society was held in Leeds on April 29. Dr J. W. A. HUNTER (Manchester) read a paper on the effect of amputation of the cervix on subsequent pregnancy and labour.

Dr Hunter made a plea for a more conservative attitude to endocervicitis and cervical lacerations in view of the increasing adoption of extensive plastic procedures in women of child-bearing age in preference to pessary treatment. A study of the literature dealing with the dangerous sequelae of cervical amputation and repair led to the conclusion that these operations in women of child-bearing age might cause sterility, repeated abortion, premature labour, or obstructed labour. His interest indeed was first drawn to the subject by seeing a case under the care of the late Dr Hugh Ferguson. The patient had had her cervix amputated previously by Emmet himself, and subsequently had seven abortions. A first and living child was at last obtained after she consented to remain in bed from the onset of the pregnancy. In the last nine months he had encountered nine further cases of abortions occurring for the first time after cervical amputation. Discussing the question of dystocia, Dr Hunter went on to describe a series of eighteen cases of labour following cervical operations. In ten the labour was uneventful, in three Caesarean section proved necessary, in three vaginal Caesarean section, and manual dilatation of the cervix was needed in two cases. There were three maternal deaths following delivery by the vaginal route, all being due to a rupture of the cervical stump extending up into the lower uterine segment.

#### Modified Plastic Operation

In an attempt to minimize the dangers of cervical plastic surgery Dr Hunter said he had devised a modification of the usual plastic technique to be used in some cases of prolapse occurring in young women, particularly those cases in which there was little cervical hypertrophy present and the length of the uterus did not exceed three and a half inches—cases in which there was relaxation of all the uterine supports. Essentially the operation consisted of one circular incision about half an inch above the external os and another one inch to one and a half inches above this, enabling a complete circle of vaginal skin to be removed. The customary anterior colporrhaphy was then performed and completed by first suturing the cervix to the vaginal skin beginning behind and working round to the front at each side. Thus the Fothergill principle of sliding the uterus upwards and backwards was maintained but with conservation of the cervix. Sometimes after the operation the uterus tended to remain in the vaginal axis. This might be remedied by opening the anterior peritoneal pouch and stitching the uterus to the peritoneum at the level of the anterior colporrhaphy or alternatively by performing a Gilliam's suspension operation.

Professor DANIEL DOUGAL said he had done a similar operation on one occasion. He advocated only a low amputation in these cases of prolapse in young women. Mr JEATFRESON (Leeds) confirmed from his own cases the increased tendency to abortion after cervical amputation. The main technical operative difficulty in dealing with this type of prolapse was that unless something was done to fix the cervix the vaginal walls tended to sag after the operation.

Mr GLYNN DAVILS (Sheffield) stressed the need for removing the unhealthy tissues surrounding the os uteri; he found that removing but a shaving of the cervix sufficed in performing the Fothergill operation. In an analysis of 400 cases he had found that only 60 per cent of the women who could have conceived after the operation did so. Mr BRYAN WILLIAMS (Liverpool) did not consider that cervical repairs had a significantly sterilizing effect, but regarded routine amputation of the cervix as quite unjustifiable in women of child-bearing age. Professor W. FLETCHER SHAW welcomed criticism of the Fothergill operation in view of its widespread adoption. He did not think the operation had a sterilizing effect, rather the reverse. In about one-third of the cases the prolapse recurred after a subsequent labour.

### NEW ZEALAND

[FROM OUR CORRESPONDENT IN WELLINGTON]

#### When an Insured Person is Not Insured

Whether tetanus, in a case which ended fatally, was an injury received when a woman fell from a motor-car, or whether it was only the result of the injuries, was one of the questions that arose in an interesting case decided by the New Zealand Court of Appeal in judgments delivered on April 29. The appeal was brought by an insurance company against the decision of Judge Northcroft, who held that the administrator of the estate of a deceased woman was entitled to recover from the company the sum of £1,000, being the amount the woman was insured for at the time she fell from a moving car and suffered slight physical injuries from which tetanus developed. Three judges allowed the appeal and one dissented.

The Chief Justice said that the correctness of the decision depended upon the true construction of the insurance policy. The policy provided that the company should pay to the insured or her personal representative

“(a) if the insured shall within three calendar months of the occurrence of the accident die solely as the direct result of the actual physical injuries received in the accident, the sum of £1,000 provided that no compensation shall be payable under Section (a) when the death is due to a disease which is the direct or indirect result of the injuries received in the accident or which may attack the insured in consequence of his lowered vitality, whether such lowered vitality is due to the accident or not or for death due to a disease from which the insured suffered prior to the accident and which has been intensified by the accident.”

The Chief Justice declared that the disease itself could not be said to be part and parcel of the “actual physical injury” received in the accident. The most that could be said, as the trial judge had found, was that at the time of the accident there was imported into the wound dirt which included germs or spores of tetanus. The case, in his opinion, seemed to be that of a disease supervening and consequent upon the actual physical injuries. In other words, the insured sustained actual physical injuries, the disease of tetanus supervened as a direct result of such injuries, and the insured died as a result of that disease. Thus the case came within the proviso. He also stated in his judgment as follows:

There is no reason why an insurance contract should not be made except on the basis of a contract of indemnity. It would not be appropriate to expect a person to be liable where the death is due to disease, and it is not clear how the death may be caused. That is exactly what has happened in this case. If I am right then even though it is a simple case of the wound at the time of the accident did not contain germs or spores of tetanus, and such information can be said to be part and parcel of the actual physical injury. The death of the insured was admitted due to the disease of tetanus which developed some days after the injury. Such a case was the direct result of the injury—that is, of the introduction of the germs or spores into the wound. The original injury had expressly protected it against liability. The death was due to a disease, even though it was not directly against liability where the death was due to an intervening disease.

The dissenting Judge held that the language of the exception or proviso in the insurance policy was in appropriate to exclude a disease such as tetanus in a case which arising from the accident, and the death of the insured was due to the disease of tetanus, and not merely a result of the injury. Tetanus was not the result of the injury, but it was itself the main injury.

### National Health Insurance

A special session of Parliament was called to discuss National Health Insurance and Superannuation. However, no such legislation was passed because the Government declared that many difficulties had to be overcome and much more consideration of the proposals was required. Therefore a special Parliamentary Committee was set up to take evidence in the recess and advise the Government. Before this committee had time to do more than begin its investigations the Prime Minister announced the Government's policy. There is to be a means test for superannuitants but none at all for the national health service. The latter service is for all rich and poor alike; it will provide no specialist treatment. The health and superannuation scheme will add a shilling in the pound to income tax and an unknown sum in addition will be drawn from the Consolidated Fund. This will assist the redistribution of wealth.

After the Prime Minister's policy was announced the Parliamentary committee continued to take evidence. Testimony from representatives of the medical profession was not very well received. The views of witnesses representing the Hospital Boards Conference were in the main at variance with the Prime Minister's proposals. A representative of the Douglas Credit Group said the whole scheme could be made to cost nothing. At present, therefore, it may be said without fear of contradiction that nobody knows in what precise way national health is to benefit. Facilities for drinking medicine will be increased and the hours extended.

## ENGLAND AND WALES

### King Edward's Hospital Fund

The Duke of Kent presiding over the annual meeting of the President and Council of King Edward's Hospital Fund at St James's Palace announced the start of the new experiment in co-operation in the voluntary hospital service of London—namely, the establishment jointly by the hospitals and the King's Fund of a central office to facilitate the quicker admission of urgent and acute cases (see *Journal* June 4, p. 1221 and p. 1325 of this issue). The annual report showed that the hospitals taken together had increased their income in 1937 by about £350,000. Expenditure had also increased however and the net result was a small credit margin of about £8,000 on a turnover of over £4,500,000. This was better than in 1936 when there was a small aggregate deficit for the first time since 1926 after which year the aggregate income of the London hospitals had increased from a little over £3,000,000 to well over £4,000,000 and the total receipts for capital and maintenance had grown to £5,000,000,

including more than £2,000,000 in voluntary gifts and over £1,000,000 contributed by outpatients. The Duke of Kent added that this result had no been attained without great personal efforts and sacrifices on the part both of hospital volunteers and of members of the public and that still greater effort would be needed in view of the increasing difficulties of the present time. But these were worth while to have were great advantages in the system of having no kinds of hospital the voluntary and the municipal influencing each other and co-operating to form a complete hospital service the voluntary hospitals emphasizing the values associated with freedom elasticity and personal initiative so important in medicine and surgery and the municipal hospitals the values associated with large scale work and centralized administration under a public authority. The voluntary hospitals were trying to increase their income and on the other hand to combine the advantages of organization with those of freedom by means of voluntary co-operation. The King's Fund had from time to time been able to help the hospitals in their efforts to develop new sources of income. Within the last two years the hospitals had agreed to the inauguration of a combined fund which had succeeded splendidly. It was announced by the Distribution Committee that it now had stock of seven cwt grammes of radium most of which was being used in various individual hospitals. A small amount was kept in a pool from which it was lent to hospitals when it was needed for a patient. The new forms of radium treatment could be developed where radium was applied in large quantities and distance from the patient.

### Home Service Ambulances

The annual report of the Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society states that the ambulances carried 161,840 patients during 1937. In the course of the year under review two new stations were equipped one at Kingston in Herefordshire the other at Ripley in Derbyshire. The report describes the notable increase in comfort and even luxury which is a feature of modern ambulances so that journeys of two hundred miles or more are undertaken without undue distress to the patient. Improvements have also been evolved in methods of loading and unloading stretchers. With regard to the x-ray department it is stated that the mobile x-ray unit is able to carry out in private houses and nursing homes radiographic work of a quality comparable to that produced by the stationary unit of a large hospital. The service provides both a high powered unit for ultra rapid chest radiography and a low powered unit for fine focus maximum detailed investigation of bones and joints. The report stresses the importance of an adequately trained personnel imbued with sympathy, knowledge and judgment. Except in times of special emergency the transference of the ambulance work of the country to municipal or national control is not advocated. It is however suggested that a fuller recognition of a service which carries a growing burden on public view is desirable on the part of local authorities especially those responsible for county administration.

### Sewage in the Mersey Estuary

In a report issued as Water Pollution Research Technical Paper No. 7 by the Department of Scientific and Industrial Research (H.M. Stationery Office 30s.) a detailed description is given of the results of a chemical hydrographic and biological investigation of the effects of the discharge of crude sewage on the amount and nature of the deposits in the estuary of the River Mersey. For many years the possible effects on the concentration of the estuary of the direct discharge of sewage from a population of nearly one and a half million people have given rise to controversy among the local interests concerned. Since 1920 to facilitate the passage of ocean-going ships the sea channels in Liverpool Bay have been deepened by continuous dredging. It had been suggested that the nature

## CORRESPONDENCE

may be shown at the site of operation on the stomach, in the abdominal wound itself, or as a post-operative pulmonary complication. In a recent series of 506 cases of carcinoma of the stomach at St Bartholomew's Hospital, which I investigated, exploratory laparotomy was carried out in 136. Of the cases explored, twenty-nine, or 21.3 per cent, died as the result of the operative intervention. This group, of course, was out of the question for radical and palliative surgery were out of the question. In the majority of cases death occurred within a week of operation, and therefore at a time when the healing of the abdominal wound was not complete. But I believe that whatever the mode of death, be it from peritoneal or pulmonary infection, it represents the failure of the normal reactionary processes to operative and anaesthetic trauma in a patient weakened and wisted by malignant disease.

What is the explanation of the good abdominal scars which Mr Riddell has noted in his cases? The healing of surgical wounds in general in relation to subsequent scar formation depends on several factors. The first of these is that the incision should be so planned that it is parallel to Langer's lines of elasticity of the skin. The second is that the incision should be at right angles to the surface of the skin. The third is that the skin should be undercut to free it from the subjacent muscles. The fourth is that reactionary changes produced by ligatures and skin sutures should be minimal. Finally, of course accurate coaptation of the skin itself is essential. This matter has been dealt with very fully in a recent article by Conway in *Surgery Gynecology and Obstetrics* (February 1938). The good scars that are obtained in patients with advanced malignant disease occur because the local fibroblastic response is subnormal, because there is usually marked laxity of the tissues and because the absence of tension in the skin itself and because the patients are often bedridden or almost so. On the other hand quite apart from operative technical considerations, the patient who gets the broad or the keloid type of scar is usually one who is fairly active or muscular, who has a fair amount of subcutaneous fat or even puts on fat after operation and one who has not an incurable or fatal disease.

The high mortality after exploratory laparotomy for carcinoma of the stomach and the good—that is, cosmetic—scars which are so often seen in those patients who survive operation are both aspects of the same phenomenon—namely a response which is less than the normal to the stimulus of operative trauma—I am, etc.,  
REGINALD T. PAYNE  
London W 1 June 7

## Treatment of Placenta Praevia

SIR—I was very interested in the excellent results in the treatment of placenta praevia recorded by Drs O Lloyd and J E Giesen in the *Journal* of June 11 (p 1258). An analysis of the results seems to show that although a plan is made for plugging the vagina the worst figures were obtained when this technique was followed. Of the ten deaths in 256 cases five were in patients so treated. I was brought up to believe in the value of vaginal plugging but it was scarcely ever done while I was Master of the Rotunda. It predisposes to sepsis and it is better to have the patient prepared for the preconceived treatment which can then be carried out without unnecessary manipulations and without plugging. I believe that every piper on placenta praevia the danger of delivery before the cervix is fully opened should be stressed especially in view of some recent communications in the

*Journal*. My views on treatment are expressed in Tweedy's *Practical Obstetrics* (Bethel Solomons and Falkiner, 1937), and it can be seen there that there were 138 cases during my Mastership with two deaths—a mortality rate of 1.4 per cent. These two deaths occurred early, and were due to errors in technique. This letter is written to praise and not to decry, and especially to point out that the excellent results of Drs Lloyd and Giesen could probably be improved if plugging were omitted. There should be no mortality from placenta praevia—I am, etc.,  
BETHEL SOLOMONS  
Dublin, June 13

## "Gonococcus Antitoxin" for Gonorrhoea

SIR—We have now taken advantage of Dr Anwyl-Davies's invitation to visit the venereal department of St Thomas's Hospital and have there examined the case records of twenty-five patients treated with "gonococcus antitoxin." We ask your permission to summarize our views on this question in the light of the additional information so obtained.  
Dr Anwyl-Davies wrote (*Journal*, March 26, p 701) as follows:

Since December 2, 1937, all the male out patients attending the venereal department of St Thomas's Hospital, suffering from acute gonorrhoea, who can attend regularly have been receiving daily doses of 1 ccm of the antitoxin as routine, with adjuvant treatment. This could not be done, nor would I permit it, were they obtaining no therapeutic benefit or experiencing the severe reactions described in such a high percentage by E T Burke *et al*.

It seems that since December, 1937, all patients receiving injections of "antitoxin" in this department have received, concurrently, sulphanilamide preparations by mouth as part of the routine adjuvant treatment. Therefore it is clear that any discussion of the results obtained in patients who began treatment after that date is irrelevant to the present controversy.

Dr Anwyl-Davies has made the following statements with regard to the results obtained in twenty-five patients who began treatment previous to that date and whose records we were permitted to examine: "the results are comparable to those already published by myself (*Journal*, March 26, p 701), and "the cases were carefully investigated, and 'prontosil or some illud substance' was not used 'by way of adjuvant'" (*Journal*, May 14, p 1069).

Analysis of these twenty-five case records reveals the following points. All these patients had urethral irritations from the first as adjuvant treatment. Two of them received 'prontosil or some allied substance' after they had failed to respond to the initial treatment. In no case did the urethritis subside during the period of "antitoxin" treatment. In fifteen cases there were records of microscopic examinations of smears from urethral discharge after the first few days, and in these fifteen the average duration of known persistence of gonococci was forty-nine days. Others had persistent purulent discharge, but there was no record of microscopic examination. The twenty-five patients may be divided into three groups, six who remain under treatment for approximately eight months, and in two of them the signs of urethritis still persist. The average duration of signs of urethritis in the other four was just under six months. Of the twelve defaulters, one defaulted after the first injection, two in the first month, three in the second month, and one after the third month, two in the fourth month, and one after the

months. At the time of default eight had persistent arthritis and four were at the stage of tests for latency. The third group consists of seven patients who were discharged as cured after periods of treatment which averaged seventy-eight days, but the tests of cure applied were not equivalent to the standard recommended by Dr. Ansell Davies (*The Treatment of Venereal Diseases in General Practice* (1935)) and we regard them as inadequate. Further analysis is limited to twenty-four patients thus excluding the one who defaulted after the first injection. The toxic effects recorded are very similar to those described by ourselves and included pyrexia up to 102° and 103° F, urticaria, joint effusions, arthralgia, malaise, headaches, pains in the back, local pains, etc. Of the total of twenty-four eleven suffered severe reactions as the result of the antitoxin injections. Four others complained of symptoms of moderate severity. Thus fifteen or 62 per cent. of these patients experienced toxic effects.

As regards complications two developed epididymitis, one acute prostatitis, and two acute posterior urethritis subsequent to injections. The complication rate was thus 21 per cent.

Tests showed evidence of latent infection in eleven out of the fifteen patients who remained under treatment until the urethritis had subsided.

It is now quite clear to us that the effects obtained by Dr Anwyl Davies in using this preparation were very similar to those recorded by ourselves and the discrepancy between our reports is one not of results but of interpretation of results. We have failed to find any justification for the claims which Dr Anwyl Davies has made on behalf of this preparation but we are content to leave it to your readers to decide which of these interpretations is more fully justified by the available facts—We are etc

E T BURKE      A H HARNNESS  
J GABE      A J KING

London W 1 May 27

SIR—We accepted Dr Anwyl Davies's invitation and on May 20 visited the St Thomas's Hospital Venereal Diseases Clinic and inspected the records of the twenty-five cases mentioned by him in your correspondence columns. In order not to cause Dr Anwyl Davies further inconvenience we were at the clinic at the same time as Drs Burke, Harkness Gabe and King but we would like to point out that our conclusions are entirely independent of theirs.

From a careful examination of the case sheets the following facts emerged

1 **Adjuvant Treatment**—All patients had urethral irrigations from the first with the exception of one patient who defaulted after the first injection two patients had protosil or some allied substance. (See *Journal* May 14 p 1069)

2. **Toxic Effects**.—Practically half of the cases suffered severe toxic effects from the antitoxin injections our criteria of severe toxic effects being the following: prexia up to 103.2 F, severe malaise in one case necessitating fourteen days in bed, severe generalized urticaria, severe pains and stiffness in the joints, diarrhoea and vomiting in several cases. Injections had to be delayed in order to allow for recuperation. Three cases suffered moderate toxic effects such as pain and swelling at the site of injection, headache, and general malaise of moderate degree.

**3 Defaulters**—Apart from the one patient who defaulted after the first injection seven out of the remaining twenty-four defaulted during the persistence of urethritis of the remaining seventeen two had persistent urethritis after eight months and in the remaining fifteen the urethritis was present on an average for over fourteen weeks in all twelve cases defaulted at various stages of treatment.

• *Complications*—Two cases developed epididymitis or acute proctitis, two acute posterior urethritis—all following antitoxin injection. This gives a complication rate of over 20 per cent.

**Tests of Cure.**—Although we found that seven cases were discharged as cured in our opinion the tests of cure in all cases were inadequate and furthermore inadequate to the standard recommended by Dr. Ansell Davies himself in his book *The Treatment of Venereal Diseases in General* (London, 1935).

In conclusion it seems obvious to us from the above facts that the results of the antitoxin treatment at the hands of Dr Anwyl Davies are almost precisely similar to those obtained by Drs Burke Harkness Gabe and King. Therefore we find it impossible to accept the claims that Dr Anwyl Davies has made for this form of treatment in acute gonorrhoea.—We are etc

### Sulphanilamide in Meningitis

SIR—I have been interested in the reports in the *Journal* recently on the treatment of meningitis with sulphamidamide and it may be of value to record my experience in Northern Nigeria, where the meningococcal type of meningitis occurs in epidemic form at the end of the dry season. This year the epidemic was especially severe and the mortality appeared to be practically 100 per cent. The cases were of a fulminating type death

supervening in three to four days as a rule. This was the case until sulphamilamide was secured from the coast and its effect on the next admission is seen in the accompanying chart the temperature remitting within twelve hours of the administration of sulphamilamide and recovery being continuous. Two prontisol album tablets were given every eight hours for three days one tablet eight hourly on the fourth day and one tablet daily for a further four days. A second case made a similar recovery and the treatment was then taken over on his return from leave by the permanent medical officer who has I believe treated about thirty more cases with results well worth recording—I am etc

## CORRESPONDENCE

## The Adrenal Cortex and Intersexuality

SIR—I have read with great interest the account given by Dr H W C Vines of the pathology of the adrenogenital syndrome in the volume *The Adrenal Cortex and Intersexuality* by Broster, Allen, Vines, *et al* (see leading article in the *Journal* of May 14, p 1056). In so doing one was struck by the fact that, with the exception of certain of the cases of Cushing's pituitary feminization (which are of course, on a different footing), feminization of the male and iso-sexual precocity in the female occur, so far as the adrenal is concerned, only in malignant conditions—that is in the so called carcinoma and adenocarcinoma of the cortex. Androgenous development alone occurs in foetal masculinization or "pseudo hermaphroditism," and there is no reliable record of the occurrence of feminization in "post-pubertal and adult virilism" of the type with cortical hyperplasia and hyperfunction. The fact that male sex hormones may have an oestrogenous effect, as is shown, for instance, by the observations of Korenchevsky (*Journal* November 6, 1937, p 896) of feminization of rats by means of the male hormone testosterone propionate, has a bearing on the general question as it could be argued that the very exceptional feminization, etc., in those cases was brought about in this way.

The facts as just adduced are significant, however, from another point of view since the occurrence of malignancy does not signify simply hyperplasia and hyperfunction, by which exaggerated normal effects are produced. I have suggested elsewhere that malignancy means essentially an alteration and mutation of the genes of the cell concerned, whereby modifications are produced in its growth, form, and function. The infinitesimally small number of cases of feminization of the male and of iso sexual change in the female could be explained thus on the basis of alteration in function from androgen to oestrogen formation, brought about by a genic change in the malignant conditions existent.

The cortex of the adrenal, androgenic in the foetus, therefore would seem to retain this capacity through life except in a small proportion of the malignant cases just referred to for the reasons stated. In view of this persistence it would appear that the existence of a neutral somatic castration such as is said to occur, for instance, in the castron is in impossibility, since the adrenal cortex would be there to sway the body to the male side.

Witsch (Allen *Sex and Internal Secretions* 1932) brings evidence to show that the cortical zone of the gonads is a female and the medulla as a male inductor. This would explain the occurrence of the androgens and oestrogens in the urine of both sexes where one sex would be represented by its corresponding sex cells and hormone and the other by hormone alone on the lines of the occurrence of androgens in the adrenal cortex. In this context it would seem that Dr Vines's statement that the sexual changes caused by these pathological states may all be referred to abnormalities of a normal mechanism of sexual development in which the gonad plays a passive part is too sweeping. Doubtless the adrenal cortex (assisted however by the medulla of the gonad) gives a male twist with corresponding vestigial of the male sex organs to a chromosomal female but there remains still to be explained the female sex organs given with corresponding vestigial of the female sex organs to a chromosomal male. It seems that the cortex could do this while a direct action possibly by means of a gland of the pituitary on this cortical zone of the

testicle in the production of feminization of the male in some cases of Cushing's pituitary basophilia has not been excluded. The annotation in the *Journal* of November 13, 1937 (p 974) on gynaecomasty and testicular function possibly has a bearing on the latter point as also on the earlier discussion on malignancy.

Although Dr Vines states that a definite claim cannot be made that the fuchsinophil substance is actually the masculinizing hormone or pro-hormone, it would be interesting to know if a positive fuchsinophil reaction is obtained in the actively functioning testicle—I am, etc.,

Aberdeen, June 2

## Psoriasis

SIR—I have recently investigated the incidence of psoriasis in the out-patient department for diseases of the skin at the Royal Northern Hospital. My results correspond so closely with those of Dr W S W Guthrie (45 per cent) published in the *Journal* of May 21 (p 1125) that I think they may be of interest.

During the five years from 1931 to 1935, out of a total of 5900 recorded new cases of psoriasis—that is, 4.4 per cent—were diagnosed as cases of psoriasis. Of these, 100, or 3.7 per cent were male and 165, or 6.3 per cent, were female. The age incidence of 253 of these cases was also investigated and is tabulated below.

TABLE I

Age in Years	0-10	10-20	20-30	30-40	40-50	50-60	60-70	Over 80
Males	9	18	24	19	11	9	6	2
Females	18	23	41	17	22	18	15	1

The youngest case in this series was a male aged 2 years the oldest was a female aged 81. It will be noted that the frequency is greatest in the age period 20 to 30 and this applies to both males and females. About 42 per cent of all the recorded cases (male and female) were between 10 and 30 years of age. Among women 53 per cent were under 30.

In Dr John T Ingram's most interesting article on some problems in psoriasis (*Journal*, April 23, p 881) it is surprising that no mention is made of the curious relation between psoriasis and joint affections or so called rheumatic pains, a subject greatly discussed, especially by French dermatologists. Whether one regards these arthropathies as being of neurogenic or of rheumatic or gouty origin and the former view appears to be more prevalent now—it is a remarkable fact that joint pains, neuralgias, and myalgias are often complained of by persons with psoriasis. The predilection of the disease for areas around joints (knees, elbows, spines, etc.) is certainly a striking concurrence, and the fact that psoriasis may be provoked by similar factors in common with the various forms of rheumatism (fibrositis, myositis, rheumatoid arthritis, osteoarthritis, and gout) is noteworthy. Both psoriasis and these forms of rheumatism are less prevalent in summer and in warm countries, both are supposed to be rare in the Tropics. A low-protein diet has been recommended for both conditions, and both are supposed to be aggravated by the excessive consumption of alcohol. Foci of streptococcal infection are held to be responsible for the acute exacerbation of both acute attacks of psoriasis. On the other hand, in well established cases of psoriasis in adults it is often impossible to find any evidence of any streptococcal focus of infection whatsoever, which is equally true about many well established cases of rheumatoid arthritis. Apart from these rheumatic associations of psoriasis, a definite syndrome—arthropathic psoriasis—

is well recognized. The fact that Crocker in this country strongly advocated the use of strychn and the same in adequate doses in the treatment of psoriasis is interesting in this respect.

A preliminary investigation of twenty cases of psoriasis with special reference to the situation of the lesions in relation to the presence or absence of localized rheumatic pains and other associated conditions is being made by the author.

TABLE II

Age and Sex	Situation of Lesions	Family History	Rheumatism	Other
1 Female (21)	Wrist, legs, hands, nails, elbows, back (none)	Nil	Nil	Dermatitis of elbows
2 Male (65)	Elbows, knees, legs, nails, feet	Nephritis	xx	
3 Male (4)	Elbows, knees	Nil	Nil	Cutaneous eruptions after measles
4 Male (41)	Elbows, knees, guttate on trunk	Mother and brother have psoriasis	Nil	
5 Male (5)	Arms, elbows, forearms, legs	Nil	Nil	
6 Female (38)	Scalp, elbows, knees, trunk	Nil	x	
7 Female (74)	Elbows, knees	Nil	x	Scaly, verrucous dermatitis of hands
8 Female (71)	Scalp, elbows, knees	Nil	x	
9 Female (33)	Scalp, arms, nails, knees	?	x	
10 Male (74)	Knees, nails, feet	Maternal	x	Variety of scaly dermatitis in both hands
11 Female (12)	Elbows, knees	Nil	Nil	
12 Female (14)	Scalp, elbows, hands, knees, spine	Nil	x	First attack began during menstruation
13 Female (31)	Scalp, elbows, nails, knees, abdomen	Nil	x	Lived in Italy, sunbathed, took malaria medicine
14 Female (70)	Scalp, elbows, nails, knees	Nil	x	First attack noticed after amputation of breast at menopause
15 Female (41)	Scalp, elbows, knees, trunk	Nil	x	First attack after confinement, severe, when worrying
16 Male (25)	Scalp, elbows, legs, body	Brother has psoriasis	x	
17 Female (65)	Elbows, knees	Nil	xx	
18 Female (39)	Elbows, knees, trunk	Mother has eczema and 11 of her brothers and sisters all had eczema	Nil	
19 Male (5)	Elbows, knees	Nil	Nil	
20 Female (22)	Elbows, knees, spine	Nil	xx	

It will be seen from Table II that heredity is not such an important factor in psoriasis as is generally stated. Only three or possibly four cases out of the twenty had any family history of psoriasis and of these only two could have inherited the disease from a parent. On the other hand no

more than thirteen cases out of the twenty gave a history of rheumatism. Admittedly the number of cases investigated in this preliminary review is small and the incidence of pains attributed to rheumatism is high particularly in patients of advanced years and of the hospital out-patient class but even so one cannot fail to be impressed with the high percentage of cases of psoriasis in which there is a history of joint or muscular pains or when actual howlings of arthritis occur.

I have to thank Dr Henry Semon FRCP for his kind permission to publish the above figures—I am, etc,  
M. J. Hill N 10 May 27 I. S. FOX.

### Stored Blood for Transfusion

SIR—I have read with interest Dr T. I. Wilson and Dr J. M. M. Jamieson's article on the use of stored blood for transfusion (*Journal* June 4 p. 1207) as we have been using stored blood here for some time and now use it almost exclusively. The advantages are obvious and I think it only a question of a short time before the practice is generally adopted. We withdraw 15 ounces of blood through a 16 gauge transfusion needle into a 20 ounce U. G. B. screw-capped bottle containing the extra and fitted with a two-way cap to enable suction to be applied and in this way can fill the bottle in under four minutes. Apart from changing the two-way cap for a sterile aluminium one which I think is preferable to a wool plug the blood is never exposed to the air. The blood is then stored at about 3°C and is warmed to about 37°C before use. We have so far experienced no reactions. The blood is filtered through gauze and clots are rarely found on the filter. A small tube of diluted citrated blood and a tube of whole blood taken before the needle is withdrawn allow cross agglutination and a Wassermann reaction to be performed without opening the bottle. We keep in stock two pints of Group 2 (A) and two of Group 4 (O) and have never had occasion to keep it longer than fourteen days.

No the least advantage is in the economy of blood donors of which only one has been used in the last twenty transfusions against the old figure of 40 per cent—I am, etc,

E. BIDDLE  
Transfusion Officer East  
Suffolk and Ipswich Hospital

Ipswich June 7

### Advertisements of Secret Remedies

SIR—Your leading article on June 4 on "The Trade in Secret Remedies" inspired by Professor A. J. Clark's book—is supplemented (whether by accident or design) by an equally apposite dissertation entitled "The Beecham Laboratories." Both articles are written with a restraint which makes them the more effective. But in these as in all other discussions on the subject no mention is made of the fact that many of the advertisements on which this lucrative trade relies make flagrant use (or abuse) of the good name in which the medical profession is held by the general public. Instances of this tendency will spring to the mind of any reader of the daily papers exemplified by such phrases as "then her doctor told her and next day at the surgery" (It is or is not to note that one never sees "then her osteopath told her or his naturopathic healer suggested.") The doctor is always unmistakably portrayed usually with his stethoscope dangling from his ears. It is within the experience and knowledge of all engaged in general practice that this pseudo professional endorsement of the manufacturer's claims is not without influence on many of our patients. How often has one deprecated the spending

of money—ill afforded—on “tonics,” etc., only to be met with the rejoinder ‘But I thought that all the doctors approved or recommended it’”

An advertisement has recently appeared in the papers by which the public is led to believe that a certain secret preparation, apparently equivalent to the Elixir of Life, the ‘discovery of an eminent doctor,’ hitherto prepared by a secret formula known only to a “limited number of medical men” and used by them in hospitals, is now available for the relief of mankind. The inference to be drawn from this advertisement is little short of a libel on our profession, imputing as it does the invention, employment, and eventual exploitation of a secret remedy by a qualified medical man.

Were this and similar advertisements associated with the name of any one practitioner it is easy to foretell what action he would immediately take. But because it is the name of us all collectively which is taken in vain no one apparently considers it to be his duty to protest.

While we are the last to resent any caricature or lampoon—even in a commercial context—we must preserve the right and owe the duty to protect our good name and reputation from that abuse on which the vendors of secret remedies endeavour to found their fortunes—I am, etc.

London W2 June 6

A G EDDISON

### Haemorrhage into Rectus Abdominis

SIR—With regard to the case report by Dr F Bedo Hobbs in the *Journal* of April 23 (p 895) on a fatal haemorrhage into the rectus abdominis muscle during pregnancy the record of a somewhat similar case recently under my care may be of interest.

The patient a white adult male aged 48 while at work on May 5 was suddenly and unexpectedly struck in the abdomen by a block of wood flying from a machine. He felt pain but was able to continue with his work for three to four hours. The pain then became so severe that he reported sick and went home. He was able to walk home—a distance of about a mile—but had several times to stop to rest. He did not sleep at all that night and I was called to see him in the morning of May 6. At this time the temperature was 100.8° F, the pulse rate 84 and the blood pressure 122/80 mm Hg. Examination of the abdomen revealed board like rigidity of the right rectus muscle with marked tenderness in the right lower quadrant. The left rectus was not in spasm and deep palpation caused only slight pain. There was no pain over the liver spleen or left kidney region. There was a slightly positive Murphy's sign over the right kidney, the liver dullness was intact and no peristalsis could be heard by auscultation. There was no blood in the urine. The patient felt sick all that day and vomited in the afternoon.

After consultation with a surgeon it was decided to watch the patient without active interference. On the following day May 7 the temperature was 100° F and the pulse rate and blood pressure were unchanged as were the abdominal signs. An occasional peristaltic wave could be heard following manipulation. The patient vomited twice. On May 8 he felt better, his temperature was 99.4° F, his pulse rate 72 and his blood pressure 120/78 mm Hg. The right rectus was less rigid and the lower quadrant was less tender. On May 9 his temperature was down to 98.4° F, the pulse rate and blood pressure being unchanged, the bowels moved spontaneously for the first time (up to then there had been no movements and cathartics and enemata had been withheld in order to allow peristalsis). The patient's abdomen was slightly less rigid and less tender and active peristalsis was heard for the first time on auscultation.

The following day May 10 the temperature rose to 100° F, again the pulse rate was 68 and the blood pressure 114/72 mm Hg. The patient was more markedly tender in

the right lower quadrant, a hot-water bag was substituted for the original ice bag. On May 11 the temperature was again normal and the pulse and blood pressure were unchanged. Rigidity was less and there was the suggestion of a mass lateral to the right rectus. On May 12 the rigidity of the rectus had passed off and a mass was definitely felt. It was round, very smooth, very tender, about the size of an orange and yielded a fluid thrill.

The next day May 13, the mass had decreased in size by about half. The temperature had been normal for several days now and remained so for the remainder of the illness. The patient's appetite was very poor during the entire time and in the later stages he complained of great weakness. A tonic was administered and his appetite and strength increased. On May 14 there was palpable in the right lower quadrant, about two inches above Poupart's ligament, a mass irregular in outline, firm, of solid consistency and with no fluid thrill, about two inches long by one inch wide, markedly tender to pressure. Two days later the mass was still present and the patient's condition was unchanged.

On May 18 the patient was very much stronger and was up and about. The mass was about half its original size. He felt very little pain and there was very little tenderness over the mass. He returned to work and has been working since. He was seen once again on May 23, when he felt quite well except for some dysuria and frequency of micturition, the mass had almost entirely disappeared. He was placed on a urinary antiseptic, and since he has not returned I expect that these symptoms have also disappeared.

In my opinion this was a case of bleeding beneath the rectus abdominis muscle, with a collection of blood between the rectus and the peritoneum. I believe that due to the severe blow, a vessel in the lower part of the muscle was torn, and as the posterior sheath is absent in its lower part, the blood collected directly between the muscle and the peritoneum and set up the peritoneal irritation that almost caused us to operate for a possible intra-abdominal lesion—I am, etc.,

Brooklyn, New York, May 27

A JAY SNYDER

### British Hospitals in China

SIR—In forwarding to you the enclosed letter, which is being addressed to all members of the medical profession and to the leading pharmaceutical manufacturers in this country, I would like to add a few notes.

When the Lord Mayor's Fund for the Relief of Distress in China first made its appeal to the public, it was realized by our central executive committee in Shanghai under the presidency of the British Ambassador and the Governor of Hong Kong that provision must be made for the application of funds for relief along three lines.

First Cases where British residents in China are rendered destitute. These are being dealt with by the British Women's Association in Shanghai.

Secondly The huge refugee problem. Here the application of relief is being carried out largely through the refugee camps of the International Red Cross Committees in Shanghai, Hankow, etc., through the Salvation Army workers in charge of rice, soup and gruel kitchens, and through the international committees in charge of refugee zones, where hundreds of thousands of women and children have sought refuge. For all these homeless and destitute, money for food and over 1,000 bales of clothing have been sent to China.

Thirdly The hospital work for wounded persons both civilian and military. Here relief is being applied through the hospitals of the various missionary societies which are working both in Chinese and Japanese controlled territory. Grants in money to enable existing hospitals to expand their bed capacity and over £15,000 worth of medical supplies have been sent out. In the

Central China area alone over twenty six British hospitals have been helped to keep going.

But the war goes on the wounding of civilians by aerial bombing is still more extensive and by cable and letter the call comes for further medical supplies. One of the most glorious pages in the history of the profession is being written by our medical colleagues in China—many of them in isolated positions carrying on as the tide of war sweeps over them and keeping their work going whether Chinese or Japanese are in control of the area in which they work. Surely the least that we who live in comfort and safety at home can do is to keep them supplied with the necessary medical stores anaesthetics antisepsics dressings drugs and instruments without which they cannot carry on. Gifts of instruments in good condition will be welcome as well as the necessary money for purchase, and may be sent to me at 121 Westbourne Terrace W2—I am etc,

H. GORDON THOMPSON  
Honorary Secretary and Treasurer  
Lord Mayor's Fund for the Relief of  
Distress in China

June 2.

\*The letter enclosed by Dr Gordon Thompson is in the following terms

You will doubtless have read in the Press the news which has been coming through from the war areas in China but it cannot give an adequate picture of the terrible suffering of the people and the need for help at the present time. Large areas have been rendered desert by complete destruction of farms and villages. Enormous numbers of the population have been on the move—men seeking for safety and others in search of food. In a great many places the chance of a harvest either this year or next has gone for farms are burnt and the beasts for ploughing implements and seed have all been destroyed.

A death rate in a refugee camp for the first few months was 250 per 1000 to a large extent among the children and this gives but a bare statistical picture of an incalculable amount of suffering and anguish both physical and mental. With summer coming on epidemic diseases such as cholera relapsing fever the dysenteries, and small pox are spreading whilst food deficiency diseases such as beriberi are becoming rampant.

British hospitals established by missions of all denominations have been nobly endeavouring to do their part in meeting the need and without a word of complaint they are being overwhelmed with the care of the sick and wounded. Since the early days of the struggle the Lord Mayor's Fund has sent out, apart from cash for starving refugees about £18 000 of medical supplies and drugs to the hospitals but these are now becoming exhausted and we must stand by our medical colleagues in this their need. [The principal requirements are set forth in the appendix to this letter.]

Much has been given by doctors, chemists and manufacturing firms. If you already have been approached for help we beg that you will not take it amiss if we make a further appeal, for stimulated by the efforts of the few we are now trying to reach everyone. We therefore confidently ask for your sympathy and active co-operation to do something for this mass of suffering. Goods in kind or money to buy drugs dressings or instruments will all be welcomed. We anticipate your sympathetic consideration and your active help. Donations of money and gifts in kind may be sent to and cheques or postal orders made payable to: H. Gordon Thompson M.D., F.R.C.S. Honorary Secretary and Treasurer The Lord Mayor's Fund for the Relief of Distress in China 121, Westbourne Terrace London W2.

## Assistance to Medical Students from Austria

SIR—I think many of your readers will agree that the suggestion made in Professor J. A. Ryles letter in the *Journal* of June 11 (p. 1256) is a little misguided. Surely sympathy and assistance should be extended in the first place to those refugees who are already practising the profession to which they have devoted their lives and who are now too old to take up another career rather than to youngsters not yet embarked on a career. There are not enough free places in medical schools for our own nationals and every year there are prospective students who state that they can only begin medicine if they obtain a scholarship. Moreover the income of many medical schools depends to a considerable extent on grants from the Government and local authorities and it is doubtful whether these schools have the moral right to expand to the disadvantage of British students money on the training of those who may not be capable of assimilation by the British Commonwealth. It has often been my experience when interviewing candidates for dental bursaries, in the days when these were enough to pay for the complete course to elicit the information that the candidate was taking up dentistry merely because a free education was offered. Our medical schools are full already why then should we encourage a further influx? If a case can be made out for any candidate of outstanding merit no doubt consideration should be given but to ask every medical school to offer a free place is sympathy run riot. Furthermore I cannot agree that by the time these students have qualified the high figure for entry into the profession will have fallen off because as medical schools are still full competition for posts at that time will be at a maximum.

With regard to the question of Austrian Jewish practitioners obtaining a quick qualification in some University in this country I do not think there is any University which will grant a medical degree under three years to any foreign graduate. There is however a licensing body whose diploma may be granted to foreign graduates after only one year provided the necessary examinations are passed and one gathers that this body is creating a certain amount of dissatisfaction not only in this country but in other parts of the British Empire because of the shortness of time in which its qualifications may be obtained—I am, etc,

G. A. CLARK

Sheffield June 11

Dean of the Faculty of Medicine

## Nutrition of Denmark During the War

SIR—Most of what Dr. Johanne Christiansen tells in your issue of May 28 (p. 1174) about consumption of food in Denmark during 1918 is incorrect. There are various wrong assertions in her letter, but not to take too much space I shall only treat one—the high consumption of meat. It is correct that Dr. Christiansen has now succeeded in persuading the Danish Department of Statistics to make a calculation showing that the consumption of meat in 1918 was greater than the normal but the truth remains that it was in fact far lower. The discrepancy is explained thus.

The Department of Statistics bases its calculations on the number of domestic animals reckoning with a normal slaughtering of beasts of normal weight. Actually the cattle were starving for lack of food and were often mostly skin and bone. Moreover the farmers secretly slaughtered many small pigs for their own use. While this of course was illegal the local authorities were unwilling to report their friends to the police. Consequently the farmers had enough

bacon while very little was available for other people. Bacon was in fact rationed—120 grammes weekly for each person—and even this amount often could not be had. No more than 200 grammes of beef was available at the normal price. If more was wanted, thrice the price had to be given. 'Meat is so expensive' wrote a leading Copenhagen paper, 'that common people cannot afford to eat it even on Sundays.' As this shortage of meat was on the verge of inducing revolt among labourers, the president of the Council for Nutrition reported to the Unemployment Committee that it was not possible to procure more than a third of the normal consumption of meat at the ordinary price.

Your readers may not find it easy to decide whom to believe. I venture to remind them that my experiments on a cheap plain Chittenden-like diet were started forty years ago and aroused so much interest that the Government granted me a laboratory for nutrition. When the blockade threatened us in 1917 with starvation, I was appointed counsellor of the Government and issued a pamphlet advising the public to live on a diet consisting mainly of wholemeal rye bread mixed with wheat-bran, potatoes, barley porridge, milk, a little butter, and very little meat and vegetables. Of this pamphlet 40,000 copies were distributed, and in 1918 I spent half my time travelling round the country giving instruction. In the discussions which followed my lectures I often heard housewives say 'That is all very well, but here we all live in accordance with your principles, we are compelled to do so.' On these journeys I had ample opportunity to observe the underfeeding of cattle and its consequences. If anyone at that time had said that people were eating more meat than usual, the statement would have raised a laugh.

After living for forty years on the low-protein diet I do not feel old at 76. Last summer I travelled on cycle from one end of the country to the other, about 80 miles a day—I am, etc.,

Copenhagen May 29

### Identicalness of Finger-prints of Enzygotic Twins

SIR—In a letter in the *Journal* of May 21 (p. 1142) I directed attention to the remarkable discrepancy in the opinions held by high medical authorities respecting the (alleged) identicalness, or total dissimilarity, of the finger-prints of uniovular twins and solicited the opinions of those with special knowledge of the subject. I quoted Dr. Leonard Williams (*Minor Medical Mysteries*) to the effect that "not only their finger-prints but the whole of what is known as the friction surfaces of their hands and feet are frequently found to be identical", and, contrarily, Sir James Crichton-Browne's concurrence with the contention of Inspector Greville's that "in finger-print identifications the authorities never make a mistake. It is impossible to make a mistake even in twins the finger-marks are totally different."

I have had no reply and still adhere to my opinion that neither the finger-prints of monozygotic twins nor of any other persons have ever been shown to be identical, despite the high authority of Dr. Leonard Williams and despite the implied agreement with his statement by Professor J. B. S. Haldane who writes in *The Inequality of Man* "Their finger-prints are generally distinguishable, but those of the right hand of one of them are more like those of his brother's right hand than of his own left." My contention was (and is) that the finger-prints of monozygotic twins are *always* easily distinguishable by experts, and that it is impossible for these specialists to err.

This question may, however, be of such importance in criminology that it is clear that it is not to be decided

on the opinion of any authority, however eminent, but upon the established facts of science. Chief Inspector Cherrill, the official in charge of the finger-print bureau at New Scotland Yard, courteously resolved the problem in the following communication, remarkable alike for its clarity and decisiveness:

In reply to your letter dated May 30, I am directed by the Commissioner of Police of the Metropolis to acquaint you that the finger-prints of twins (including uniovular) are as dissimilar as those of other persons who are in no way related.

The fallacy that the finger-prints of twins are identical arises through the superficial examination of the prints by persons who are not finger print experts.

It often happens that the finger prints of twins are similar in pattern but this is often the case with prints of any other persons. Finger print identification, however, does not end with similarity of pattern, but is attendant solely upon the coincident sequence of the papillary ridge characteristics and these have never been found to agree in prints taken of different fingers whether of the same person, twins, or any other persons.

According to Sir Francis Galton, the chances of any two finger-prints proving identical are less than 1 in 64,000,000,000. There is not any flaw in what has been known to experts for many years to constitute "the most infallible identification system in the records of criminology"—I am, etc.,

Liverpool, June 5

ROBERT COTTER

### "Spontaneous Human Combustion"

SIR—The subject of spontaneous combustion apparently attracted the attention not only of the medical profession but of the laity one hundred years ago. In chapter I of *Jacob Faithful* published in 1834, Captain Marryat gave a vivid account of the spontaneous combustion of the hero's mother. The following passages come from his description:

The lamp fixed against the after bulkhead with a glass before it, was still alight and I could see plainly to every corner of the cabin. Nothing was burning—not even the curtains to my mother's bed appeared to be singed. There appeared to be a black mass in the centre of the bed. I put my hand fearfully upon it—it was a sort of unctuous pitchy cinder. As the reader may be in some doubt as to the occasion of my mother's death I must inform him that she perished in that very peculiar and dreadful manner which does sometimes although rarely occur to those who indulge in an immoderate use of spirituous liquors. Cases of this kind do indeed present themselves but once in a century but the occurrence of them is but too well authenticated. She perished from what is termed *spontaneous combustion*—an inflammation of the gases generated from the spirits absorbed into the system.

Note that Captain Marryat quoted five of the six points mentioned by Dr. L. A. Parry (*Journal*, June 4, p. 1237):

(1) The victim was a chronic alcoholic. (2) She was an elderly female. (3) In the cabin there was a lamp which might have occasioned the fire. (4) Little damage was caused to the combustible things in contact with the body. (5) There was a residue of greasy ashes. Captain Marryat did not mention that the hands and feet escaped combustion. Evidently there were doubts as to the origin of the fire, for 'after much examination, much arguing and much disagreement the verdict was brought in that she died by the visitation of God.'

One can picture the temperance fanatics making much of the phenomenon of spontaneous combustion and pointing out the foretaste in this world of the fate which awaits the drunkard in the next—I am, etc.,

GAVIN THURSTON M.R.C.P.

Clapham Common, S.W. 4 June 8

## Atrophic Rhinitis

SIR—I am indebted to Dr James Adam (*Journal* June 4 p 12.6) for calling my attention to the fact that in my article on the treatment of atrophic rhinitis (May 28 p 1167) I did not make it sufficiently clear that patients with atrophic rhinitis are only susceptible to pulmonary tuberculosis. I did not mean to imply that tuberculosis was an aetiological factor. I cannot agree with Dr Adam when he says that atrophic rhinitis is the result of undiagnosed sinusitis and that the treatment of the sinusitis cures atrophic rhinitis. I have searched a large number of these cases for proof of sinusitis by antral puncture and by x-ray examination and have not found any indication of sinusitis. In my opinion, and that of a large number of my colleagues there is no aetiological connection between the two conditions. The problem of atrophic rhinitis is much more difficult than the treatment of sinusitis. It is significant that true atrophic rhinitis has been much less common in recent years since the great improvement in the feeding and housing of the hospital class of patient. It is true that a pseudo-atrophic rhinitis does occur occasionally after severe operations for chronic sinusitis. I hope that Dr Adam's letter will stimulate the continuance of the investigation of the aetiology of atrophic rhinitis and its relation, if any, to sinusitis—I am etc.,

## UNIVERSITY OF LONDON

The entry fee for the MB BS examination under the revised regulations is £15 15s—that is £5 5s for each of the three parts. Part I will be held for the first time in November 1938 and Parts II and III in May 1939.

The first two paragraphs of the regulations for the MSc examination Branch I (*Red Book* 1937-8 pp 289-90 *Blue Book* September, 1937 p 833) were amended to read as follows

"A candidate for the degree of Master of Surgery Branch I must have taken the degrees of Bachelor of Medicine and Bachelor of Surgery in this University. The candidate must forward to the Registrar in form (1) a certificate of having held for at least two years an approved surgical appointment or appointments at a hospital with an associated medical school recognized for this purpose. In special cases the University is prepared to approve a candidate whose appointment in a special surgical clinic at a hospital as one of the two years' experience referred

to above and (2) a record of operations performed by him signed by the surgeon or surgeons under whom he has worked.

The Senate on May 18 awarded the degree of PhD in Biochemistry to A E Kellie (Lister Institute of Preventive Medicine).

The following appointments were made. Mr Philip Turner to represent the University on the Educational Board of the British Social Hygiene Council. Dr R A Young to represent the University at the twenty fourth Annual Conference of the National Association for the Prevention of Tuberculosis to be held in London from June 30 to July 2. It was reported that as a matter of urgency the Vice-Chancellor had nominated Dr A M H Gray and Mr W Girling Ball for appointment to represent the University on the Council of the London (Royal Free Hospital) School of Medicine for Women. Sir Cooper Perry has been appointed representative of the University on the governing body of the Battersea Polytechnic Training School for 1938-9.

Lieutenant Colonel H E Shortt has been appointed to the University Readership in Medical Parasitology tenable at the London School of Hygiene and Tropical Medicine and is assigned to the Faculties of Medicine and Science.

The following candidates have been approved at the examination indicated

## UNIVERSITY OF SHEFFIELD

At its meeting on June 10 the Council appointed Professor G A Clark MD the representative of the University on the General Medical Council.

The Council accepted with regret the resignation of Dr Duncan Cameron of the post of honorary demonstrator in anatomy and accorded him its thanks for his services to the University.

## Obituary

### JAMES CHAMBERS M.D., MCH

By the death of Dr James Chambers, at his residence in Highdown Road, Roehampton, the medical profession, and especially the Royal Medico-Psychological Association has lost one of its outstanding members. His early life was at Belfast. He took the M.A. of the Royal University of Ireland in 1882, the L.R.C.P.I. in 1885, was senior scholar, first medical scholar, and Dunville Student

at Queen's College, Belfast, and won the first medical exhibition of the Royal University of Ireland. For many years he was the resident physician to The Priory, Roehampton. He became an ordinary member of the Royal Medico-Psychological Association in 1882, was assistant editor of the *Journal of Mental Science* in 1900-5, and co-editor 1905-14. He was president in 1913-14 and treasurer during the period 1917-31; his presidential address was "On the

#### Prevention of the Insanities

Dr Chambers was formerly lecturer on mental disease at the Middlesex Hospital Medical School, became consultant in mental disease to the London military hospitals and physician to the special hospital for officers at Latchmere House, Ham Common. He had been a member of the British Medical Association since 1887, and when the Association held its Annual Meeting in London in 1895 he acted as honorary secretary of the Section of Psychology and in 1901 he was vice-president of the Section of Psychological Medicine at the Cheltenham Meeting.

Since his retirement from The Priory a few years ago Dr James Chambers had been gradually failing in health, and at last passed peacefully away on June 7. The deepest sympathy is expressed to Mrs Chambers and her sons and daughters. To those of us who were familiar with his kindness and constant care for patients under his treatment at The Priory it is a great sorrow that Dr Chambers should have passed away after such a long and trying illness, always borne with the greatest fortitude.

R. PERCY SMITH

### V. H. WYATT WINGRAVE M.D.

The death of Dr Vitruvius H. Wyatt Wingrave took place at Lyme Regis on June 1, just two days after his eightieth birthday. His was an example of indomitable will-power over a very prolonged period of chronic illness. Added to this after some attacks of Meniere's symptoms he became stone deaf. I remember him pathetically telling me he would never hear his children's voices again. Furthermore he was attending an out-patient in the Central London Throat, Nose and Ear Hospital and while her throat was being examined the patient accidentally coughed violently in his face, setting up an acute inflammation in one of his eyes which left him permanently blind in that eye. He retired to Lyme Regis in 1920.

He was born in Coventry in 1858, the son of Joseph Wingrave, a chemist, and Jane, daughter of James Wyatt of Leamington. He married three times and leaves two sons and a daughter by his second wife. He was educated at Coventry Grammar School and at the Middlesex Hospital, taking the L.S.A. in 1882, M.R.C.S. in 1886, and proceeding to the M.D. Durham in 1900. He became lecturer in physiology at Cooke's School of Anatomy, which position he held for twenty-five years. After passing through various posts in the Central London Throat, Nose and Ear Hospital, he eventually found a congenial home in the hospital's pathological laboratory. The fact of the matter was that his complete deafness terribly handicapped him in his profession. It was also a constant danger to him, and twice when crossing the street unattended he was run over. On one of these occasions I was summoned to attend him, and I came away with the impression that he bore a charmed life, for anyone else would most probably have been killed. In the pathological laboratory he did excellent work and some special research work on the connexion between tuberculosis and nasal disease. He became also pathologist to the Medical Graduates Club and President of the British Laryngological and Otological Association. He was a Fellow of the Palaeontographical Society, and in 1928 presented to the Royal College of Surgeons Museum specimens showing rheumatoid disease in extinct saurians. He was an original thinker, and was in many ways an extraordinary man. Being an omnivorous reader with a colossal memory his knowledge became encyclopaedic and there was hardly a subject in science or art with which he was not intimately conversant, and he would enter into any discussion with a scholar's knowledge and enthusiasm. I remember when one of my sons and I were paying him a visit at Lyme we were one day standing with him on the Cobbe and watching cartloads of ballast being removed from the beach to the Cobbe for purposes of strengthening the sea's defences. He had been talking about Monmouth's rebellion and had pointed out that the place on the beach from which they were removing the stones was the very place where they had erected a gibbet for hanging the rebels. At that moment he stooped down and from some of the rubble picked up—a human patella! It looked for all the world as if it were to corroborate what he had been saying.

On January 13 of this year Dr Wyatt Wingrave was presented with the honorary freedom of Lyme Regis, but on account of his illness the Mayor, with a little speech, was obliged to hand him the scroll in his study. That this honour was to be paid the *Times* (November 10, 1937) had already given notice. Dr Wingrave had been the founder of, and honorary curator to, the Lyme Regis Museum for ten years until ill health had prevented him from continuing. He had taken the keenest interest in the geology of the district and he discovered a rare form of ammonite and was the first to describe it. Scientists courteously gave it the name of *Oryoceras wingravei*. Dr Wingrave had previously received the freedom of his native city—Coventry. The funeral service took place at Coventry Cathedral on Saturday, June 4, and a memorial service was held at St Michael's Church, Lyme Regis on June 6.

T. WILSON PARRY

The unexpected death on May 31 at the age of 59 years, of Dr WILFRED ALEXANDER STEEN removes from the medical community of Ilford and district a practitioner of unusually wide repute, a colleague of unswerving loyalty and a character distinguished by its generosity and broad humanity. The youngest son of the Rev George Steen of Keady, Co. Armagh, Wilfred Steen came

to London at an early age and started immediately his medical course at the London Hospital qualifying before he had reached the age for admission to the *Register*. Undoubtedly he received in these early years material encouragement from his eldest brother—James Ross Steen—who was already well established in practice first in Poplar and later in Ilford where Wilfred ultimately joined him. The two brothers were gifted with a rare clinical instinct and a faculty for organization and these combined with an assiduous application to work resulted in their building up a practice of unusual dimensions. Ross Steen died in January 1934 and was at the time of his death the senior practitioner in Ilford and now Wilfred S. En—probably claiming a similar distinction in point of seniority—passes from our midst mourned not only by a number of colleagues intimately associated with him in practice but by the local medical profession as a whole to many of the younger members of which he extended valuable help and encouragement. His death will also be much regretted by a host of patients and a large circle of friends to whom he was affectionately known as Wilfred. His friends will always cherish memories of his unstinted generosity a generosity equalled only by his invigorating sympathy as a doctor. Those who knew him most intimately at work marvelled at his patience and his ability to deal with a difficult situation by his timely joke and by the soft answer which turneth away wrath. It had often been said of him that he was never heard to give expression to an unkind word about anyone and this tribute was paid to him on one of the two occasions when he held in consecutive years the presidency of the Ilford Medical Society. There are many who will have a sense of personal loss in the passing of so genial a personality. He had been a member of the British Medical Association since 1910. To his widow and their son Pit—not long survived his curriculum as a medical student—there will be a volume of sympathy in their great bereavement.

## Medical Notes in Parliament

### Epidemics of Milk borne Diseases

On June 1 the Ministry of Health circulated statistics on epidemics of milk borne disease from 1933 to 1937 as under

Place	Year	Disease	Notifications	Deaths
H	1933	Scarlet fever	43	4
W Ham-pest	1933	Paratyphoid B	24	1
Epsom	1933	Paratyphoid B	22	None
Chesham	1935	Scarlet fever	48*	6
E. 7	1935	Scarlet fever	100	2
Area of 2 UD and 3 free dist. distinct	1936	Eritema, forearm (cakes thought to be vehicle)	9 cases in UD and 23 in district	1 death among the 9 UD cases. Deaths in district not stated
Barnborough, Pooe and Chesham	1936	Enteric	718	51 among the residents. No information as to visitors
D. 100000	1936	Scarlet fever and tonsillitis	135 cases of scarlet fever 24 of 1 case throat	2 deaths definitely associated with the outbreak
W. 7 (Wills)	1936	Gastro-enteritis	About 100 (disease not notifiable)	None

### Pensions for the War-Disabled

On the motion for the White-tinted adjournment Mr TINKER opened a debate on the treatment of ex-Service men. He asked that a psychologist should be called in to examine claimants and he criticized the treatment of pensions appeals

After discussion Mr RAMSBOTHAM said the war disabled man meant the man in respect of whom there was reasonable evidence that the disablement had a war origin. In appeal cases the independent medical expert was generally a Hurler Street physician or surgeon who did the work at a small fee and performed a great service for the country. In most cases the expert did not want to see the man because the question was not one of diagnosis but of the perusal of all the documents in the case and of the war service records. The independent medical expert had to decide whether there was reasonable evidence to connect the present condition of the man with the war service shown on his records. This must be primarily a medical decision. It he induced the medical officers of the Ministry to relax their medical examination and their standards of evidence, the pensions system of the country would never recover.

**Veneral Disease Clinics**—Mr GALLACHER asked on June 2 whether the remuneration of medical officers in attendance at veneral disease clinics in London was fixed on the basis of the number of attendances per medical officer. Dr ELLIOT in reply said he was informed by the London County Council that the remuneration of medical officers at clinics at present participating in the veneral diseases scheme for London was not determined on the basis indicated. Mr GALLACHER further asked whether the monetary grants made to veneral disease clinics in the London area were made in proportion to the total individual attendances in the course of a year instead of to the number of patients treated. He suggested that this was calculated to lead to over treatment which in these diseases could be almost as dangerous as no treatment. Dr ELLIOT said he was informed by the London County Council by whom the payments were made that the number of attendances was only one of many factors taken into consideration in determining the amounts of the payments. The question of altering the basis of the grants did not therefore arise.

Mr GALLACHER on June 2 asked what were the circumstances in which St Paul's Hospital lost its grant of £8,000 from the London County Council leading to its having to close down several wards and why no public inquiry was held into the events which led to this action being taken. Dr ELLIOT answered that the grant referred to was payable by the London County Council to St Paul's Hospital in pursuance of arrangements made annually between the county council and the hospital for the diagnosis and treatment of veneral diseases. In reviewing their veneral diseases scheme for the year 1937-8 the county council decided that it was no longer necessary to continue the arrangements with St Paul's Hospital. The discontinuance or renewal of such arrangements was a matter within the discretion of the county council.

**Blood Tests for Paternity**—Answering on June 2 a suggestion by Sir Ernest Graham Little that magistrates should be informed by circular of the validity and value of blood tests, Sir SAMUEL HOARE said further action on his part was not called for. The courts were aware of the value of the tests.

### Notes in Brief

The service of salaried midwives under the Midwives Act 1936 may now be said to be in effective operation throughout England and Wales though there is a small number of areas in which the local authorities have not finally completed their arrangements with other bodies.

The Secretary of State for Scotland is considering the report of the committee of inquiry appointed to examine the request submitted by the Scottish Universities for a grant from the Education (Scotland) Fund, and hopes to announce a decision at an early date.

The numbers of insured men and women in Great Britain between the ages of 35 and 65 at January 1 1938 were about 1,000,000 and 400,000 respectively. Of these about 105,000 men and 50,000 women were then in receipt of disablement benefit.

Of 176,466 houses affected by lum clearance orders, 104,600 had been abolished by the end of 1937.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 4, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

## EPIDEMIOLOGICAL NOTICES\*

## Small pox

On June 9 a case of small pox was reported at Graveland and admitted to the Isolation Hospital. In recent weeks 2000 people in the town have been vaccinated.

During the week ended June 4 there were 12 (9) cases of small pox with 10 (10) deaths reported in Hong Kong. During the same week 5 cases with 3 deaths were notified in Burma—2 (67) cases with 44 (53) deaths in Calcutta 272 (291) cases with 55 (52) deaths in the Presidency of Bombay 26 (38) cases with 14 (7) deaths in the Presidency of Madras and 92 (100) cases with 15 (20) deaths in Siam. In Indo China in the same week 55 cases of small pox were reported in Tonking and 4 in Hanoi.

## Enteric Fever

During the week under review there were 31 notifications of enteric fever in England and Wales compared with 17 in the previous week—of these 4 (2) were in London—1 each in Bethnal Green Islington Kensington and St Pancras. In Scotland 16 cases of enteric fever were notified—2 more than in the previous week. 13 were cases of typhoid fever 7 of which occurred in Roxburgh County belonging to the Hawick outbreak 4 (1) in Glasgow and 1 each in Ayr County and Perth and Kinross County. There were no deaths from enteric fever in Scotland during the week.

## Diphtheria and Scarlet Fever

In England and Wales notifications of diphtheria during the week under review dropped from 1002 to 986 while in London they rose from 128 to 139. There was a marked drop in notifications for Scotland and considerable increases were noted in Eire and Northern Ireland. Deaths in the 126 Great Towns of England and Wales fell from 29 to 24 and in London from 5 to 2. Of the 24 deaths from diphtheria recorded in the 126 Great Towns 4 each occurred in Liverpool (2) and South Shields (0). There were 6 deaths from diphtheria in Scotland during the week under review—the same number as the previous week—3 of which occurred in Glasgow (2) and 1 each in Edinburgh (1) Clydebank (0) and Ayr (0). There was a fall in the notifications of scarlet fever in England and Wales during the week—2048 to 1967—and in London from 218 to 188—the figures for England and Wales were slightly in excess of the median value for the last nine years but for London they were appreciably less. In the Great Towns of England and Wales 6 deaths were recorded from scarlet fever compared with 3 in the previous week, while in London the number was the same—namely 1. In Scotland there were during the week 3 (0) deaths from scarlet fever. Notifications in Scotland rose from 362 to 396 while in Eire they fell from 112 to 103, and in Northern Ireland from 114 to 91.

## Primary and Influenzal Pneumonia

Notifications of primary and influenzal pneumonia were lower both in England and Wales and in London for the week under review than they were in the previous week—919 as against 1082 in England and Wales and 72 as against 82 in London—both these figures however are in excess of the median values for the last nine years. Fewer deaths from influenza were reported in England and Wales—London and Scotland during the week. In the West Riding (Yorks) 107 (140) cases were notified of which 35 (44) were in Sheffield 19 (24) in Leeds and 18 (12) in Bradford. In Warwickshire there were 59 (61) cases of which 36 (36) were in Birmingham. Of the 180 (186) cases reported in Lancashire 53 (49) were in Liverpool and 43 (42) in Manchester. There were 38 deaths from influenza in the 126 Great Towns of England and Wales during the week of these 5 (2) were in Birmingham and 3 each in Liverpool (1) and Man-

chester (2). In Scotland 240 cases of primary pneumonia were notified compared with 246 in the previous week—there were 3 cases of influenzal pneumonia (6 more than in the previous week) and 1 death which occurred in Coatbridge. In Eire there were 14 deaths from pneumonia of which 8 (9) were in Dublin and 2 (2) in Limerick. There were 10 (13) deaths from pneumonia in the ten principal towns of Northern Ireland during the week 6 (11) in Belfast and 2 (1) in Portadown and 1 each in Londonderry (1) and Lurgan.

## Measles and Whooping-cough

In the 126 Great Towns there were 20 deaths from measles compared with 16 in the previous week—of these 16 (6) occurred in London and 1 each in Acton Brentford and Chiswick Enfield Tottenham Barnsley Kingston upon Hull Leeds Newcastle upon Tyne St Helens Sheffield Stockton on Tees Exeter Rhondda. During the week 512 cases were reported from the L.C.C. elementary schools compared with 949 in the previous week. The average daily admissions to the L.C.C. fever hospitals were 31 compared with 46 in the previous week and the number of cases of measles under treatment in these hospitals on Friday June 3 was 1171 compared with 1252 on May 27. On the same day there were under treatment in the L.C.C. fever hospitals 1012 (1009) cases of diphtheria 824 (841) cases of scarlet fever 259 (272) cases of whooping-cough. Notifications for the week ended June 4 in the eleven metropolitan boroughs in which measles is notifiable were 341 (460) distributed as follows: Battersea 14 (45) Bermondsey 3 (20) Finsbury 13 (35) Fulham 23 (55) Greenwich 96 (104) Hampstead 28 (18) Lambeth 61 (45) St Pancras 76 (74) Shoreditch 18 (20) Southwark 14 (23) Stepney 20 (23). In Scotland 271 cases of measles were notified compared with 380 in the previous week—the figures for Glasgow were 65 (121) Dundee 68 (65) Kirkcaldy 43 (57) Lanark County 20 (45) Falkirk 25 (38) Edinburgh 17 (13) Aberdeen 14 (44). During the week there were 10 (11) deaths from measles in the 16 principal towns of Scotland—of these 4 (5) occurred in Dundee 2 (4) in Glasgow and 1 each in Aberdeen (2) Paisley (0) Greenock (0) Coatbridge (0). In Northern Ireland there was 1 death from measles in Londonderry County Borough and in Eire there were 4 deaths all in Dublin.

In England and Wales there were 13 (11) deaths from whooping cough during the week under review of which 2 (3) occurred in London. In Scotland 102 cases of whooping cough were notified compared with 80 in the previous week while the deaths remained at 2—1 each in Glasgow and Kirkcaldy. In Northern Ireland 18 (16) cases of whooping cough were notified with no deaths compared with 5 deaths in the previous week.

## Cholera

During the week ended June 4 13 cases of cholera were notified in Shanghai and 2 cases with 1 death in Hong Kong. In the same week in Burma 11 (6) cases with 6 (4) deaths were reported in Calcutta 122 (102) cases with 37 (55) deaths in Bombay 16 (9) cases with 4 (3) deaths in Delhi 42 (41) cases with 19 (31) deaths in Cawnpore 13 (2) cases with 5 (4) deaths in Allahabad 2 (2) cases with 2 (1) deaths. In Indo China during the same week 162 cases were reported in Annam 375 cases in Tonking 35 cases in Hanoi.

## Plague

During the week ended June 4 there were 4 cases of plague with 8 deaths reported in Burma—in British India in the same week 3 cases with 2 deaths were notified in Bombay (Presidency) and 2 cases with 1 death in Madras (Presidency).

## Typhus

During the week under review 2 cases of typhus were reported in Alexandria and 11 in Cairo—in Palestine in the same week 2 cases were notified—1 each in Haifa

\* Except where otherwise mentioned figures in parentheses refer to the week preceding the one under review.

and Jaffa During the previous week—that is, week ended May 28—185 cases with 21 deaths were reported in Morocco, mainly distributed as follows Chaouia, 45 cases, 6 deaths, Marrakesh, 36 cases, 6 deaths, Oued Zem, 35 cases, 6 deaths, Rabat, 24 cases, 2 deaths, and 9 each in Casablanca and Dukkala During the same week in Tunisia there were 78 cases of typhus notified, mainly distributed as follows Tozeur 21, Susa 16, Suk-el-Arba 12, Gafsa 10 During the week ended May 14 136 cases of typhus with 7 deaths were reported in Poland distributed mainly as follows Wilno, 34 cases, 1 death Stanislawow, 26 cases, 2 deaths, Lwow, 16 cases 1 death, Wolhynia 16 cases, 1 death, Nowogrodek, 12 cases Warsaw, 9 cases During the week ended May 7 in the United States of America 32 cases of typhus were notified—Georgia 11, Florida 9, Texas 8, and 2 each in Alabama and North Carolina

## Medico-Legal

### A FRAUDULENT CONCERN EXPOSED.

Medical men in this country who have suffered from the predatory activities of what the Americans term the 'book agent' will be interested in the resounding defeat in India of a Mr M S Cohen, sole proprietor of the "Dominion Research Foundation"

A gentleman who claimed that he had been defrauded by Mr Cohen's concern into paying Rs 125 in instalments brought a successful action\* in the court of the principal city civil judge of Madras and asked for his money back. The evidence showed Mr Cohen's methods very clearly. An agent visits the victim and says he represents the

"Dominion Research Foundation," which has been started to link up the research which scholars are doing all over the world and which hitherto has been largely unco-ordinated. The "Foundation," he says, is a society which has as its members eminent physicians, scientists, and scholars all over the world. Membership is open to certain selected persons—of whom the 'prospect' is naturally flattered to be considered one—and a member has the benefit of the pooled research of all the others. This is contained in the 'New Educator Encyclopaedia,' which is kept up to date by a quarterly extension service. The agent's proposal is that the 'prospect' shall join the Foundation and receive the ten volumes of the encyclopaedia as a free gift. For the sum of Rs 250, payable in instalments the member is supposed to receive the quarterly extension service for ten years, with loose-leaf binders and the benefits of membership of the 'New Educator Bureau of Research' for the same period. These benefits are the educational benefits and privileges of the Bureau for research and special information, and an answer to one inquiry a week on any subject within the scope of the encyclopaedia. The member undertakes to give his unbiased opinion on the value of the encyclopaedia and service. If the fish bites, the agent produces a blue form and a white card. The card says, "I will accept one of your complimentary sets of the New Educator Encyclopaedia and agree that after delivery of same to me I will give you my unbiased opinion of the value of the said reference work and service. Even if the prospect signs the card the matter goes no further unless he also signs the blue form. Under this he agrees to buy the encyclopaedia, and becomes entitled to certain services. A white form is also shown, but it is never used. It gives the price of the encyclopaedia as Rs 210 and the price of the services at Rs 33 a year for ten years, a total of Rs 540. Its only purpose would appear to be to make members think they are getting special terms, as selected people under the blue form. On the back of the form a paragraph says that much of the value of the extension service and the research privileges for which

the member has been enrolled will come from his personal relationship with the "Foundation," and requests his help in "tying the service as closely to his personal and business problems as possible."

Having imprudently signed the contract, the victim duly gets his encyclopaedia. If he has any discrimination in these matters he will be seriously disappointed, for it has very little relation to scientific research. Except for its front page, which has been changed to bear the name "Dominion Research Foundation," it is merely a work called the "American Educator," which was prepared for school children, especially in America. The information is meagre, elementary, and often quite inaccurate. The quarterly supplements, which are to be filed in the loose-leaf binders, have nothing to do with the encyclopaedia and are mere journalistic matter. Like the encyclopaedia itself, they come *en bloc* from Chicago, and they bear the title "World Topics Quarterly, Loose Leaf Extension Service—a condensed record of important events and developments of special interest throughout the world," with the name of United Educators, Inc., Chicago.

The quality of the answers to the one question a week which a member is allowed was not tested by the plaintiff in this action, as he asked no questions. A witness from the "Foundation" said that one Dalal of Bombay, who had become a member in 1935, had been constantly asking questions and that the "Foundation" had spent Rs 3,500 in obtaining opinions for him, that one Pushpraj had asked three questions, the answers to which had cost Rs 5 each, and that one Hansotia had also asked a large number of questions. He stated that opinions were being obtained from prominent people like Mr Alfred Topham, K C, Mr Susil C Sen (a lawyer) of Calcutta, and others. The judge could not find from this evidence that the concern was seriously engaged in obtaining opinions and advice for its members, and he was inclined to believe the suggestion that the three inquisitive members had some sort of understanding with the company and that their inquiries were merely so much eye-wash.

The judge was impressed by a clause in the blue form, "This agreement is not subject to cancellation and will not be affected by any representations, warranties, or stipulations not endorsed hereon." Such a clause, of course, can never have legal effect, and, to quote the judgment, "the very existence of the clause is clear evidence of the scheme being fraudulent." Taking all the circumstances into consideration, the judge found that the entire scheme was conceived and planned in fraud and carried out by fraud. There was no society, body of persons, or institute—only Mr M S Cohen. There was no research staff, merely a few clerks in an office in Calcutta, peddling some worthless books and pamphlets. The judge found the evidence wholly insufficient for him to hold that the "Dominion Research Foundation" had any connexion with any scheme, fraudulent or otherwise, in England or elsewhere. Nevertheless, it bears a strong resemblance, in form and method to a concern to which we have from time to time referred in these columns and to which we shall refer again if necessary.

### IMPULSE AND INSANITY

The law on insanity and criminal responsibility is blamed for many injustices, by which persons whose crime is obviously due to mental disorder are punished as though they were fully responsible. A difficult problem may also, however, be created by the medical view of a criminal's mental state.

Mr Justice Humphreys had before him at the Old Bailey on May 19 a man of 40 named O'Sullivan who pleaded guilty to the attempted murder of a small boy in Epping Forest. The man had got into conversation with the boy, pulled a piece of string tightly round his neck, and gone away. He had then telephoned to the police saying he had found a boy in the forest who had been suffocated. The police found the lad semi-conscious and rescued him and O'Sullivan later gave himself up. He had had five previous convictions.

\* Thiruvengatachari v. Cohen 1937/420

had been given ten years penal servitude at the Old Bailey in 1925 for wounding with intent to murder and later had been sent to Broadmoor. Dr Grierson, medical officer at Brixton Prison, said that the prisoner had been certified insane during his sentence. While in Broadmoor he had it was understood suffered from delusions. He thought he had to murder young children especially those whose parents could not bring them up properly in order to ensure their eternal salvation. After leaving Broadmoor he had been sent to Brixton Mental Hospital and was discharged in 1935. Dr Grierson said he thought O'Sullivan invented his delusions to avoid imprisonment. He seemed quite unable to find his feet and rehabilitate himself and would perhaps sooner be in a mental hospital than at large. He would not certify him as insane on the available evidence. The judge suggested that the desire to be in a mental hospital seemed in odd relation to attempting to murder a boy and asked whether he could not go in at any time as a voluntary patient. Dr Grierson agreed but said he would not be there very long.

#### *The Judge's Comments*

The judge remarked that O'Sullivan was an extremely dangerous person to be at large and ought to be shut up in a lunatic asylum rather than in prison. It was one of those cases which gave a great deal of trouble to those who had to sentence prisoners who admitted their guilt. It was difficult to understand why the prisoner had committed the act but the act was plain. Sentencing the prisoner he said that O'Sullivan had been let loose on society and whether as a result of his discharge or not had committed the second act. He did not want to treat the prisoner as he would a vicious criminal like an armed burglar but as he had no power to send him to a lunatic asylum he could only send him to prison. If it were there found that he ought to be detained in a mental institution rather than in a place of mere punishment the authorities had ample power to take the necessary steps. All the judge could do was to ensure that for a period of years O'Sullivan could not attempt to murder someone else through his impulse whether it arose from criminality or insanity.

The published report of the case suggests that the prisoner was a psychopath and that the medical officer's difficulty arose from the tendency of a certain type of patient to show his insanity intermittently. Undoubtedly many patients behave rationally in the protected environment of a mental hospital or even of a prison and cannot stand the pressure of life outside but react in some anti-social way with the purpose often quite unrealized of getting under cover again. Once inside they cannot be called certainly insane. There was no doubt that O'Sullivan was a public danger. Perhaps such difficult problems of delinquency will only be solved when prisons become really reformatory and provision for mentally or table prisoners can be made without the rigid formality of certifying them insane.

#### AN IMPERSONATOR CONVICTED

One Lionel William Weekes was convicted last month before the Resident Magistrate of Nairobi of making a false declaration for the purpose of procuring a passport and with posing and practising as a doctor. He made out a passport declaration form under the name of William Edwin Weekes and stated that he was a physician. He put a signboard outside his house in Nairobi with the inscription 'Dr W E Weekes'. Pleading guilty he said that when he came to the country he had no intention of posing or practising as a doctor. The police agreed that in his five years in Kenya he had worked at various mission stations and done quite a lot of surgery and there had been no complaints against him. He said he really did know his job as he had been within four months of his final examination when he had taken up a position. He was fined 200s with one month's imprisonment in default. He owes an apology to the real doctor William Edwin Weekes who is on the Colonial list of the Medical Register and practises at Exeter, Ontario.

## Medical News

Professor John Beattie will deliver three Arris and Gale Lectures at the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C. on June 24, 27 and 29 at 5 p.m. His subject is 'Recent Work in Experimental Surgery'. The lectures are open to medical practitioners and advanced students.

Dr Robert Hutchison, President of the Royal College of Physicians of London and consulting physician to the hospital, will present prizes to successful students of the London Hospital Medical College on Thursday, June 30 at 3 p.m.

H.R.H. the Duchess of Gloucester will open an exhibition of photographs illustrating African progress in Kenya at the Imperial Institute, South Kensington on Monday, June 20 at 5 p.m.

The Prosser White Annual Oration before the St. John's Hospital Dermatological Society will be delivered by Professor Charles Flandin at the Royal Society of Medicine, 1 Wimpole Street, W. on Wednesday, June 22 at 5 p.m. His subject is 'Recent Advances in Leprosy and the Methods Adopted for Dealing with the Problem in France'.

The thirteenth annual Macalister Lecture will be delivered at the National Temperance Hospital on Thursday, June 30 at 9 p.m. by Dr Leonard Williams whose subject is 'This Mortal Coil'. All medical practitioners are invited to be present, and may bring friends (ladies or gentlemen). Smoking tea and coffee.

The eighth meeting of the Conferences of the International Committee of Military Medicine will be held at Luxemburg from July 1 to 4. Official acceptances have already been received from twenty-five nations. In addition to the various technical discussions, consideration will be given to the sanitary organization involved by a mobilized nation and the protection of the civilian part of the community. Various excursions are being arranged. Fuller details of the programme of this meeting may be obtained from Colonel Voncken, Office International de Documentation de Médecine militaire, Liège.

The International Congress of Light will be held at Davos in Switzerland on July 29 and 30 under the presidency of Dr Morikof. The subjects for discussion will be light and climatology, the action of natural and artificial light on healthy organisms and physiological and physical study of the therapeutic sources of light. Further information can be obtained from the secretary, Dr Schreiber, Robert Koch Platz 1, Berlin.

On Thursday, June 23 at 5.30 p.m. the Marchioness of Carisbrooke will open the new premises of the Children's Centre of the Institute of Child Psychology at 6 Pembridge Villas, W. and at 6.30 p.m. Mr Kenneth Lindsay, M.P., Parliamentary Secretary to the Board of Education will open an exhibition of the work of the institute. The chair will be taken by Professor Winifred Cullis.

The Industrial Eye Injuries Committee of the Royal Eye Hospital has arranged an exhibition dealing with the prevention of industrial eye injuries. This will be opened at the hospital on Wednesday, June 22 at 3.15 p.m. by the Earl of Athlone, K.G.

H.R.H. the Duchess of Kent has consented to become President of The Babies Club (Chelsea), 35 Danvers Street, S.W. 3. This is the first infant welfare centre for the better-to-do classes; there are now three others in London.

The fourth international postgraduate course on x-ray diagnosis for physicians and surgeons will be held at Munich from July 8 to 14. Further information can be obtained from Akademie für ärztliche Fortbildung, Robert Koch Platz 2, Berlin N.W. 7.

Dr Fred M. Smith, professor of medicine at Iowa University, has been appointed editor of the *American Heart Journal* in succession to Dr Lewis Conner, professor of clinical medicine at the Cornell University, New York, who has retired after acting as editor since the establishment of the journal in 1925.

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR BRITISH MEDICAL JOURNAL BMA HOUSE TAVISTOCK SQUARE WC1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, BMA House Tavistock Square, WC1, on receipt of proofs. Authors overseas should indicate on MSS if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, BMA House, Tavistock Square, WC1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are  
EDITOR OF THE BRITISH MEDICAL JOURNAL *Atiology*  
*Westcent London*  
SECRETARY *Medisecra Westcent London*

The address of the BMA Scottish Office is 7 Drumsheugh Gardens, Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh) and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18 Kildare Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin).

### QUERIES AND ANSWERS

#### Snoring

Z asks for suggestions for curing snoring. My patient is a healthy young man aged 30. He has led an open air life and is accustomed to sleep very soundly. He has always snored and hitherto it has been merely amusing—but he has recently married. He has no nasal obstruction or enlarged tonsils. He can snore on his side as well as on his back—he is even able to snore with his mouth tied up. Is there perhaps some sort of self retaining speculum for keeping the jaws open?

#### Human Embryos Wanted

Dr MARY CRIPPS writes to thank those readers who very kindly forwarded specimens of early human embryos. As she still requires a few more from the fifth to the seventh week of pregnancy she will be glad of even preserved specimens from retiring colleagues who have no further use for them. Specimens should be addressed to her at the Histological Department, Royal College of Physicians, Forest Road, Edinburgh. They must be packed in accordance with Post Office regulations.

#### Income Tax

##### *Expenses—Schedule E*

Major R.A.M.C. explains that he is allowed 4d per mile for the use of his car while on duty but regards that rate as insufficient to cover the cost. Can he make a claim to deduct the balance as an expense for income tax purposes? Also can he not claim a deduction for the cost of professional books?

The allowance is governed by the Rule in Schedule E that deductible expenses must be incurred wholly exclusively and necessarily in the performance of the duties of the office. It is settled law that this does not extend to the cost of travelling from the residence to a fixed place of employment but only to travelling about while on duty. Consequently it happens frequently that the income tax allowance is smaller than the total cost of running a car, the latter covering private or semi-private use and sometimes the use of a more expensive car than is necessary. What our correspondent would have to do to succeed would be to show that 4d a mile was inadequate for the necessary official use and so far as our experience goes such an attack

on the employing authority's rate of allowance would not succeed before the Income Tax Commissioners. The question of professional literature came up in the case of *Simpson v Tate* and in deciding in favour of the Revenue, Rowlatt J said: 'All taking in of professional literature and all that sort of expense which enables a man to keep fit for what he is doing are things which can none of them be blamed. That decision would conclude an appeal against our correspondent.'

### LETTERS, NOTES, ETC.

#### The Horse-shoe Club

In 1930 there was instituted an exchange of resident house physicians between the Children's Hospital and the General Hospital, St. Louis and the East London Hospital for Children (now the Princess Elizabeth of York Hospital for Children). To commemorate this association of medical workers on both sides of the Atlantic and to cement the friendships that had been made, a club called 'The Horse-shoe Club' after a popular game played at St. Louis, was founded, and held its first meeting in May, 1932. This year it was felt by some of the founders that the membership was not representative enough and that it had not the power for bringing together the American and British peoples that it could have if it were to consist of all medical men and women who had worked and resided in each other's country. And as a start at the creation of this larger organization a dinner was held at the Langham Hotel which was attended by British medical men and women who had studied in America or who have been concerned in providing study facilities in this country for American colleagues and by those who have been instrumental in providing financial and moral assistance for this type of work. Several American colleagues at present resident in London also attended. At this dinner those present were unanimous regarding the desirability of the aims of the club. Dr Geoffrey Bourne who was elected chairman suggested that to make the most of the organization there should be two branches complementary to one another, one in America and one in England. So far as the British branch of the club is concerned it will consist of three types of members: (a) medical men and women who have studied in America under a scholarship or otherwise for a period of at least six months; (b) medical men and women who grant facilities for American research workers in their departments; (c) non-medical men and women who give moral or other support for facilities for the above work. The honorary secretary Dr Leonard Findlay, 14 Wimpole Street, London W1 would be glad to hear from anyone who is eligible for membership. The subscription is one guinea per annum.

#### Death from a Wasp Sting

Dr F. ALEXANDER (Wraybury Bucks) writes: I was called to a riverside bungalow on Bank Holiday at midnight to see a lady aged 56 who had been stung by a wasp. She was dead on my arrival and had been so for half an hour or more. She had been sitting in the lounge after supper when two queen wasps flew into the room. The patient took off her shoe and knocked them to the floor. She thought both wasps had been killed. A few minutes later when she stepped across the room she trod on one of the wasps with her bare foot and was stung on the big toe. She complained of much pain and about twenty minutes later she collapsed and died without regaining consciousness. It is very seldom that a wasp sting proves fatal in such a short time but I believe the sting of a queen wasp is always more poisonous than that of an ordinary one. As the patient was suffering from cardiac disease and hyperpiesis this may have accounted for her collapse.

#### Medical Golf

The eighth spring meeting of the Sussex Medical and Dental Golfing Society was held on the links of the Crowborough Beacon Golf Club on June 5. The Rolls-Royce Cup was won by P. G. Roberts with a score of 88-17=71 and A. R. Elliott was second with 81-8=73. The afternoon round was a 4 ball foursome against bogey, which was won by A. C. Rumsey and P. G. Roberts with a score of 3 up and J. McWhirter and F. N. Strange were second with 2 up.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

206

### Psittacosis

E. HAUGEN and G. MAUER (*Deutsch. med. Wschr.* April 15 1938 p 561) give an account of the laboratory examinations for psittacosis conducted at the Robert Koch Institute during the year ended September 30 1937. It seemed at first that the prohibition of the import of parrots in 190 would do much to stamp out the disease more especially when the legislation of 1934 imposed certain restrictions on the sale and purchase of parrots. But these measures have been partly nullified by the fact that infected birds remained carriers while seemingly quite well and also by the versatility shown by purchasers of parrots in giving wrong names and addresses and so rendering difficult the tracing of suspect birds. In the year under review the laboratory findings were positive in nine of the eighty three samples of sputum examined. None of the twenty four samples of suspect blood gave a positive finding and this was also the case with the fourteen throat swabs examined. Gargled water in four suspect cases yielded one positive result in this particular case the examination of the sputum had proved negative. A negative laboratory report cannot therefore invalidate a clinical diagnosis in a well defined case but in a clinically ill-defined case a positive laboratory finding is most useful. The authors deplore the lack of any specific serological treatment and they note that chemotherapy is also ineffective. Treatment must therefore be purely symptomatic.

### 507 Constitutional Factor in Agranulocytosis?

R. RAYMOND C. IMBERT and J. R. DESHOLLES (*Sang.* 1938 12 : 327) believe that there is a constitutional familial factor in the pathogenesis of agranulocytosis. They describe the fatal case of a woman aged 23. In her childhood she had suffered from numerous attacks of severe epistaxis later the epistaxis was more frequent during the premenstrual period. The mother one sister and one brother all showed anaemia with leucopenia—particularly a polymorphonuclear leucopenia—thrombopenia and a tendency to haemorrhages. The authors regard these relatives of their patient as potential cases of agranulocytosis. The predisposition to this disease in this family seems to have been transmitted by the females as the oldest child, who died, and the two younger had different fathers. The patient her mother her sister her maternal grandmother and a maternal aunt also had either acquired or hereditary syphilis.

### 508 Urticaria from Inhalation of Milk Protein

P. HANSEN (*Ugeskr. Laeg.* March 3 1938 p 226) cannot find in the literature any reference to urticaria due to the inhalation of finely divided milk, although the consumption of milk is well known to cause urticaria in certain persons. He gives an account of a dairymaid aged 27 who had worked in a dairy for some thirteen years during six of which attacks of urticaria had grown more and more frequent. They never troubled him on holidays and occurred only when he was at work. The attacks were independent of his food and the consumption of milk products failed to provoke them. They were at times very severe and accompanied by a feeling of slight suffocation. No signs of disease were demonstrable on his admission to hospital but as soon as he was put back for about half an hour into one of the rooms of the dairy urticaria appeared. Violent cutaneous reactions were obtained to most of the substances including various milk proteins commonly used for allergic skin tests and it was therefore impossible to incriminate any one exciting factor. But

when he was tested by the spray inhalation of one component after another of milk and of the chemical employed in the disinfection of the dairy it was found that urticaria appeared only in response to the inhalation of fine particles of fresh whole milk, sour milk, buttermilk and to a less extent of skimmed milk. The lively urticaria provoked by the inhalation of a spray of cream could not have been due to its fat content as no reaction followed the intracutaneous injection of an emulsion of cream fat.

509

### Post vaccinal Orchitis

I. H. ALANAR (*Mscr. Kinderheilk.* 1938 72, 5 and 6 390) describes a case of orchitis following vaccination. The patient was a boy of 3 months bottle fed on a mixture of cow's milk and rice water. After a first vaccination which was unsuccessful he was revaccinated fourteen days later. A normal reaction followed, but seven days later he was admitted to the author's institute with high fever and swelling of both testicles. Without any treatment the fever gradually abated the swelling decreased, and in four days had completely disappeared. The author discusses the various possible explanations of this occurrence and comes to the conclusion that in spite of the fact that it happened after a previous abortive attempt at vaccination this was not an anaphylactic phenomenon but must be regarded as directly due to the vaccinia virus.

510

### Pyloritis

F. BACH (*Fortschr. Ther.* March 1938, p 127) discusses the aetiology and treatment of heartburn. He maintains that this is not invariably due to hyperacidity but may on the contrary occur in the presence of normal acidity and even of achlorhydria. Many diverse factors contribute to the causation of pyloritis the two most important of which according to Bach are abnormal sensitivity of the oesophageal and gastric mucosa and also muscular spasms particularly of the pylorus. The author reports on the results obtained in treatment with a new preparation, Siodan, which contains a spasmolytic buffer of low acidity. Thirty patients were treated. In many cases the acid secretion curve showed the objective improvement while in all cases the subjective symptoms were completely relieved.

511

### Atypical Addison's Disease

H. REINWEIN (*Med. Klinik.* March 25, 1938 p 381) found that adynamia was the most frequent symptom in masked cases of Addison's disease. Lymphocytosis was practically constant but leucocytosis was never found. The blood sedimentation rate was generally slightly increased. The blood content of sodium chloride was diminished and achylia was usually present. Reinwein points out that in atypical cases of Addison's disease the symptoms are often attributed to myocarditis. In the former the blood pressure is lowered and radiographically the heart appears small and narrow. Long febrile periods are also uncommon in Addison's disease. Disturbances of the gastro-intestinal tract with abdominal pain and diarrhoea sometimes mask Addison's disease. Hypernephromata may give rise to symptoms similar to those of Addison's disease.

512

### Avitaminosis B<sub>1</sub> in Alcoholic Polyneuritis

P. GOVAERTS (*Scalpel.* Liege March 5 1938, p 289) discusses the part played by vitamin B<sub>1</sub> deficiency in the aetiology of alcoholic polyneuritis. He points out the similarity of the nervous hepatic and cardiac symptoms of alcoholism to those of beriberi which is admittedly due to deficiency of this vitamin. STRAUSS (*Amer. J. med. Sci.* 1935 189 378) showed that alcoholics could be cured of polyneuritis by large doses of vitamin B<sub>1</sub> by mouth and parenterally even while they were continuing

to consume considerable quantities of whisky Joliffe, Colbert, and Joffe (*ibid*, 1936, 191, 515) found that in alcoholics with polyneuritis the supply of vitamin B<sub>1</sub> was insufficient, that when there was an adequate ingestion of vitamin B<sub>1</sub> no neuritis developed, and that neuritis developed in several weeks if the vitamin B<sub>1</sub> in the diet was reduced, and in seven days if the vitamin lack was absolute. There are two factors in the production of neuritis: lack or imperfect assimilation of vitamin B<sub>1</sub> and an unknown hepatic factor. In the absence of vitamin B<sub>1</sub> the disintegration of carbohydrates intracellularly is arrested at the stage of formation of pyruvic and lactic acid and these products accumulate in the tissues. Their presence in excess has been noted in the nerve centres in pigeons with B<sub>1</sub> deficiency polyneuritis. This explains the fact that excess of carbohydrate in the diet favours the development of polyneuritis when the diet is already deficient in vitamin B<sub>1</sub>.

### 513 Myelitis following Rheumatic Fever

A. MORCH CHRISTENSEN (*Hospitalsindende*, April 5, 1938, p. 327) gives a detailed account of two patients—a newspaper vendor aged 46, and an engineering apprentice aged 18—treated in the neurological department of the municipal hospital in Copenhagen for disease of the spinal cord (myelitis) which had developed after typical rheumatic fever. He discusses the frequency of such a sequel and comes to the conclusion that it is quite rare whereas chorea minor and the so-called “cerebral rheumatism” are comparatively common. He notes however, that in the *Journal de Médecine de Lyon* for 1936 (p. 315) Bouchut, Froment and Ronzier have collected twelve such cases of myelitis following rheumatic fever, some acute, others chronic. Although in the author's second case considerable improvement was achieved complete recovery could be claimed in neither case.

### 514 Acute Aniline Poisoning

J. CATHALA, R. HAZARD, H. MASCHAS and R. JEQUIER (*Ann de Méd*, March, 1938, p. 187) report the case of a child, aged 18 months who drank a quantity of shoe-stain containing an aniline dye. The main symptoms of poisoning were vomiting, convulsions, hyperpnoea, cyanosis and periods of violent excitement. Dehydration was marked. The liver was enlarged and symptoms and signs of bronchopneumonia appeared. In spite of treatment the child was in a dying condition when she was removed from hospital by her parents. The authors have carried out experiments on rabbits in an endeavour to determine if the acidosis and lowering of the alkaline reserve which they found in this case could be directly attributed to the action of aniline, and if the hyperpnoea was due to the direct action of aniline on the nerve centres. They found that in addition to the production of methaemoglobin, aniline causes a disturbance of the acid-base equilibrium and of the blood sugar level. Unfortunately these changes are not always in the same direction, so that no precise indication as to treatment is given. Aniline affects the nervous system directly, causing asthenia, hyperpnoea, somnolence, excitement, coma, and collapse. These symptoms cannot be explained solely by the methaemoglobinaemia or by the alteration in the acid base equilibrium.

### 515 Habitual Hyperthermia

C. V. MEDVEI and V. STERN (*Wien klin Wschr*, March 18, 1938, p. 326) review the problem of habitual hyperthermia, which manifests itself by a body temperature above normal, up to 99.5° F or even 99.7° F, in apparently healthy individuals. The authors classify this condition into (1) hyperthermia caused by focal infection, (2) hyperthermia without infection which may be due to a disturbance of the vegetative nervous system or to hyperthyroidism or to a combination of both (neurothyroidism). 1348 B

origin) and (3) mixed forms, which may be either simultaneous or successive. Lund distinguishes between cases of protracted post febrile hyperthermia, where the infective process still persists in an attenuated form, and cases of post-febrile hyperthermia without residual infection. In the first group the temperature returns to normal after the administration of a dose of pyrimidon, whereas the cases of the second group are uninfluenced by pyrimidon, but return to normal spontaneously on the resumption of normal habits. In exceptional cases, however, the temperature fails to return to normal even after large doses of pyrimidon, although there may be definite evidence of persistent infection.

## Surgery

### 516 Surgical Treatment of Coronary Disease

A. OCHSNER and M. DE BAKRY (*New Orleans med surg J*, March, 1938, p. 520) gives the results obtained by the various surgical procedures used in the treatment of 172 cases of coronary disease. There are three main methods of surgical attack: by operation directed at the sympathetic nervous system by thyroidectomy, and by the development of a collateral blood supply to the heart. The first procedure is based upon interruption of cardio-sensory and motor pathways. Sympathectomy is indicated for patients who are obviously poor risks. These are usually elderly people with marked sclerotic changes and fibrotic myocardial degeneration. It is also suitable for patients who have very severe pain, or in whom the angina is aggravated by emotional disturbance rather than by effort, and for those cases in which the basal metabolic rate is very low. Paravertebral alcohol injection has an almost negligible mortality and the technique, which is relatively simple is fully described. Thyroidectomy has a much higher mortality but the proportion of successful results is also higher. This method of treatment is indicated for patients who have a normal or high basal metabolic rate, who are relatively good risks, and whose angina is one of effort rather than of emotion. Treatment of coronary disease by the development of a collateral circulation has a 50 per cent mortality and is suitable for patients who have had a recent thrombosis, or show little evidence of arteriosclerosis or fibrotic muscular degenerative changes. It is suggested that improved technique and a careful selection of cases may reduce the high mortality. In the whole series reviewed a little over 70 per cent of cases showed improvement to a greater or lesser degree.

### 517 Gas Gangrene

F. KOCH (*Hygiea*, Stockholm, March 31, 1938, p. 194) has undertaken a study of the twenty-four cases of gas gangrene, six of them fatal, observed at a surgical hospital in Lund, Sweden, during the seventeen-year period from 1920 to 1936. In as many as nineteen cases the gas gangrene was associated with compound fractures, and in two other cases with injuries from accidents. In the remaining three cases it was associated with a secondarily infected diabetic carbuncle, with senile gangrene, and with the operation wound in a case of incarcerated hernia. During the same period some 700 cases of compound fractures and serious injuries to the soft tissues were treated in the author's hospital, where the frequency of gas gangrene could accordingly be put at about 3 per cent. There were also 193 amputations of the limbs for senile gangrene, diabetic gangrene, emboli, or varicose ulcer in the same period. While the mortality from gas gangrene during the great war was about 40 per cent, and remained in peace-time until 1932 as high as 42 per cent, there has since been a change for the better, and Brundberg's survey, published in 1937, showed a mortality of about 32 per cent. In all the author's cases admission to hospital was effected within two and a half hours of the accident, and

the routine surgical treatment consisted of careful wound to let and irrigation with chloramine or hydrogen peroxide. Anti-tetanus serum was invariably given unless the patients had already received it within the last two or three years. As many as nineteen cases were treated by amputation and of the five patients receiving no more radical treatment than incisions only one died.

## 518 Nailing Limb Fractures

E. CHRISTIDI (*Zbl. Chir.* March 5, 1938 p. 529) states that in Rumania nailing of fractures of the epiphyses in children, or the ends of long bones in adults, is often adopted with satisfactory results. Projection of the nail through the skin has not been found to favour infection and the projecting nail is much more easily removed than that inserted subcutaneously. Except in fractures of the neck of the femur the nail used is 8 cm. long and 2 mm. in diameter. After reposition of the fragments through an adequate skin incision two nails are driven in obliquely—and crossing each other obliquely—from the epiphyseal side, and often a third is introduced entering the diaphysis. One end of each nail projects between the stitches or through a specially made slab. After operation a light plaster bandage is applied for ten days and movement is then begun; the nails are taken out between the twentieth and twenty-fifth days. It is said that redisplacement never follows nailing and that infection or pseudoarthrosis have not been seen. The cases illustrated include fracture dislocation of the head of the humerus, supracondylar fracture of the humerus, epiphyseal dislocation at the lower end of the radius and compound tibiofibular fracture near the ankle. Residual loss of movement is said to be particularly slight.

## 519 Prevention of Post-operative Thrombosis

W. KNOTT (*Zbl. Gynäk.* March 26, 1938 p. 679) discusses the results obtained in the prevention of post-operative thrombosis and embolism by raising the foot of the bed. In the years 1933 to 1935 after the 630 operations performed at his hospital the patients were given sympatol, but the beds were not raised. There were twenty cases of embolism—six of which proved fatal—and in the same period four cases of phlebitis and ten of thrombosis. In the period 1935 to 1937 the patients received the same medical treatment but the foot of the bed was raised 25 cm. on wooden blocks. In these two years 670 patients were treated and there were only five cases of embolism (four fatal) and one of phlebitis. There were however thirteen cases of thrombosis.

## 520 Ulcus Cruris

S. TAPPEINER (*Derm. Wschr.* March 26, 1938 p. 353) describes a new method of treatment of intractable ulcus cruris. The ulcer is first cleaned by alternate applications by compresses of a 1 per cent solution of boric acid and a weak solution of hydrogen peroxide. When the ulcer has been sufficiently cleaned it is scarified and painted repeatedly with a 2 to 5 per cent solution of silver nitrate until healthy granulation tissue appears. The hard rim which often surrounds these ulcers and which is the cause of an inadequate blood supply is opened by means of numerous deep radial incisions. After about a week the ulcerated area is ready to receive a Thiersch graft. The graft is taken from the thigh of the opposite healthy limb. Just before the skin grafting the ulcer is again scarified. The denuded area on the thigh and the skin graft on the leg are covered with silver foil which encourages epithelialization and checks secretion and tetor. The author gives further details of his method of treatment and stresses the importance of after-treatment in view of the tendency of the ulcers to recur. Of ten cases treated by this method six were permanently cured, in two cases the ulcer recurred, and two cases remained unimproved.

# Therapeutics

## 521 X-Ray Treatment of Lobar Pneumonia

E. V. POWELL (*J. Amer. med. Ass.* January 1, 1938 p. 19) reports results of x-ray therapy in 104 cases of acute lobar pneumonia; only five of the patients died. In broncho-pneumonia (number of patients treated not specified) x-ray therapy was responsible for a reduction of the mortality from 30 to 13 per cent. X-rays should not be applied before the stage of consolidation. The author used rays produced at 135 kilovolts and filtered through 3 mm. of aluminium; 250 to 350 r units were applied anteriorly or posteriorly over an area slightly larger than the involved portion of the lung. If the temperature and the leucocytosis have not dropped to normal within thirty-six to forty-eight hours, a second treatment is given to an opposite field. The improvement usually sets in within a few hours after the treatment. So far the only contraindication seems to be a definite leucopenia, such as is encountered occasionally in patients with post-influenzal pneumonia.

## 522 Pernicious Anaemia

L. HEILMEYER (*Med. Klinik* February 18 and 25 and March 4, 1938 pp. 209, 249 and 295) discusses the diagnosis and treatment of pernicious anaemia at the present day and at his instance six German authorities, as well as Meulengracht of Copenhagen and Röhr of Zurich have dealt with certain specified questions. From the answers the following conclusions may be drawn: (1) In diagnosis halometry is valuable and reliable when megalocytosis is well marked; measurement of the colour index and examination of the stained blood film are more generally reliable; sternal puncture although decisive, is rarely necessary. (2) Gansslen's finding that in some cases minimal liver doses are effective is confirmed, but is regarded (even by Gansslen himself, one of the contributors) as of more scientific than practical importance and is useful in pharmacological assessments. (3) Stomach and liver preparations are equally effective. Meulengracht reckons that a year's treatment by a dried detrital and pulverized preparation of pig's pyloric mucosa costs 230 Danish crowns and by liver extract given orally 750 crowns on an average. Henning advocates a combination of intrinsic factor from antral glands (3 to 5 grammes daily) with extrinsic factor from vegetable proteins. Vitamin therapy alone is never effective. (4) It is to an increasing extent recognized that in the causation of nervous symptoms additional aetiological factors are concerned such as iron and vitamin B deficiency; occasionally striking therapeutic successes are noted from vitamin B therapy. Hoff distinguishes between first funicular myelosis developing gradually and resistant to therapy, and on the other hand symptoms due to small or large intracerebral bleeding—symptoms which occur relatively acutely and respond to treatment of the anaemia. (5) A syphilitic aetiology may now be rejected and Addisonian anaemia from liver disease (for example cirrhosis) rests on a doubtful basis. (6) True pernicious anaemia may occur (although very rarely) in pregnancy and is then curable by liver. (7) Megalocytic hyperchromic anaemia apart from a few cases of endemic sprue does not occur as a dietary deficiency disease in Central Europe. The principles of treatment, as laid down by Heilmeyer and generally endorsed by the contributors are as follows. The urgent case is given one or more blood transfusions, rightly grouped and in quite small doses and at the same time daily injections of campolon or a similar preparation in large doses. With appearance of the blood crisis parenteral administrations are gradually reduced in amount and frequency and supplemented by raw liver. In their subsequent

career the patients show great individual variations in their requirements of liver. Rarely interruptions last for years in spite of no treatment at all. Some patients do well on "depot treatment"—single injections of large doses of a concentrated liver extract at intervals of one to eight weeks. Others require continued oral administration. Regular medical supervision is required and routine examination will at some time reveal incipient nervous symptoms in a surprisingly large proportion of cases—50 per cent or more according to some. A considerable number of patients, especially women, have a combination of hyperchromic and hypochromic anaemia, the former first responding to liver but the total anaemia not responding until the latter has been treated by large doses of ferrous iron. A ferrous salt of ascorbic acid has lately been much used.

### 523 Local Vitamin A for Radiodermatitis

H. SOHIER and L. GINIEYS (*J. Radiol. Électrol.* March, 1938, p. 112) report a case of severe ulcerative radiodermatitis which had resisted all forms of therapy for six years. The ulceration, which affected the epigastric region supervened as a result of repeated radiographic examinations. Among the treatments unsuccessfully tried were diathermy, ultraviolet irradiation, heliotherapy, local serotherapy and all kinds of ointments and antiseptics. Infra-red irradiation had a definite analgesic effect. Insulin was applied locally with partial success. Vitamin A was then applied directly and caused rapid cicatrization and epithelialization of the ulcer.

### 524 Cardiospasm

J. DOBERER (*Wien Klin. Wochschr.* April 1, 1938, p. 384) contrasts cases of slight cardiospasm yielding readily to the passage of a sound and antispasmodic medication with the more common severe cases, in which the patient's suffering may be so great as to cause suicide and in which the incidence of carcinoma is twenty five times greater than in the normal oesophagus. He describes three long standing cases, with marked wasting, treated successfully by dilatation with the 'cardiodilator' described by Professor Stark, of Karlsruhe, in 1934. This is made entirely of metal and has a thin shaft, towards the end is an expanding dilator manipulated from the handle and terminally it is provided with a 'pathfinder' which is screwed on and consists of fine rubber tubing filled with mercury. Sudden and forcible stretching is requisite, so that the muscular ring, beneath the mucous membrane is torn. A ductile ring may require repeated dilatations before it can be torn.

### 525 Alcohol Therapy of Traumatic Shock

G. D. OBRASTOSOV (*Vestnik khirurgii imeni Grekova* (Russian) 53, 140, 10, 123) found that persons suffering injury while under the influence of drink stand the traumatic shock much better than sober persons. He was able to confirm this observation experimentally on rabbits. For the treatment of shock the author used either a 42 per cent alcoholic liquor given by the mouth in quantities of 70 to 100 ccm or an intravenous infusion of 200 to 500 ccm of a 10 per cent solution of alcohol. The experiments on animals have proved that the crushing of limbs which usually causes shock in untreated animals, does not produce a fall of blood pressure in drunk rabbits. The alcohol therapy of shock was ineffective only where there were multiple injuries incompatible with life. In cases of acute traumatic haemorrhage the proper treatment is blood transfusion but even in these cases the administration of alcohol as a preliminary to blood transfusion may prove useful.

1348 D

## Anaesthesia

### 526 Pantocain Spinal Anaesthesia

H. ZUMIELDE (*Zbl. Chir.* April 9, 1938, p. 791) has found the 10 per cent hypobaric solution of tropacocain satisfactory for operations below the umbilicus, though it cannot safely be used in the Trendelenburg position and its effect lasts only about an hour. An excellent hypobaric solution effective up to three hours is pantocain L, the makers (IG Farbenindustrie) of which have now produced a preparation of the dry salt in ampoules of 10 mg. This is dissolved in 3 to 4 ccm of cerebrospinal fluid obtained by puncture between the third and fourth lumbar vertebrae and reinjected, it is recommended that the injection be made rather quickly in order to mix the heavy solution with the cerebrospinal fluid. The patient is placed on his back with the head raised, and anaesthesia is usually complete in fifteen minutes. Though the level may be controlled by altering the position of the patient the author has not attempted to obtain anaesthesia above the level of the umbilicus. He reports favourably on sixty cases aged from 40 to 85; his failures were in the younger persons, and he considers the method unsuitable below 40 years. Of the sixty, fifty-three were completely successful and two total failures, in five supplementary anaesthesia was required. Only one case of collapse occurred, and this responded promptly to coramine. Two cases of severe headache were successfully treated by the intravenous administration of 40 per cent urotropin. An advantage of the method is that patients can get up on the day of operation.

### 527 Divinyl Ether Anaesthesia

E. W. BEACH (*Anesth. & Analges.* March-April, 1938, p. 90) has carried out 1,852 more administrations of divinyl ether, for eye, ear, nose, throat, and oral surgery, since previously reporting on 2,632 administrations, and he continues to find it a safe and satisfactory agent. His patients' ages have ranged from 2 to 84 years, and the duration of anaesthesia has been up to thirty minutes. It has been used alone, as a supplement to avertin or nitrous oxide and oxygen, and as a preliminary to ethyl ether. Its advantages are quick induction, easy control, and prompt recovery without nausea or vomiting. Considerable practice is necessary to obtain the best results owing to its high volatility and rapid action; the respiratory signs of depth of anaesthesia are the most important. Adequate oxygenation must be ensured. A mixture of 25 per cent divinyl ether with 75 per cent diethyl ether has been used in a number of cases, and has certain advantages over either anaesthetic used alone. The divinyl ether in the mixture does not evaporate early, as might be expected, but its effect is prolonged throughout the anaesthesia.

### 528 Nitrous Oxide

E. RYDBERG, H. HALDBO and A. LAURIDSEN (*Ugeskr. Laeg.* March 24, 1938, p. 303) have investigated at the maternity department of the Rigshospital in Copenhagen the claims made on behalf of a new Swedish apparatus, called 'sedator', for the administration of nitrous oxide during labour. It provides a graduated supply of pure nitrous oxide which the patient regulates herself. As she inspires atmospheric air between the inhalations she administers to herself during labour pangs she avoids deep anaesthesia, asphyxia, and marked cyanosis. The authors' report on their first 100 confinements thus treated shows that the results were most satisfactory in sixty to sixty-five cases, in a score of which labour was rendered almost completely painless. In many cases, however, it was found advisable to give chloroform

towards the completion of labour and there were fourteen or fifteen patients who derived little benefit from the nitrous oxide. This may have been so because some of them lacked the necessary self control or intelligence to make the best use of the apparatus. The nitrous oxide was given on the average for three hours and in some cases for five to eight hours. There were two stillborn babies whose deaths were evidently unconnected with the anaesthetic and three who were slightly asphyxiated at birth. All the other babies cried vigorously as soon as they were born. There was no delay in the birth of the placenta. The only disquieting observation concerned two cases in which pains became suddenly very frequent. But this condition did not amount to tetany of the uterus and it could be promptly checked by a small dose of morphine. Several cases of this complication have already been observed in Stockholm by other obstetricians testing the new apparatus.

529 M. RAPIN (*Schweiz. med. Wschr.* April 9 1938 p. 378) outlines the history of nitrous oxide anaesthesia and points out that it is very little used in Switzerland although it has been so popular for many years in England and the U.S.A. He has carried out about 100 administrations of nitrous oxide and oxygen sometimes with ether for minor operations particularly in children. His results have been good and he has had no accidents. He recapitulates the well known advantages and drawbacks of the gas—for example the rapid induction and recovery without after effects absence of toxicity or inflammability preservation of the laryngeal reflex etc. On the other hand, the anaesthetic is unsuitable for children under 5 years its use has not spread owing to difficulties in the supply of a pure gas and of suitable apparatus in the past. The technique of administration is not so difficult as has been sometimes suggested and he recommends the beginner to try it on himself in the presence of a third person. In laryngology he particularly recommends it for curing adenoids guillotining tonsils incising drums, anal puncture and opening peritonsillar abscesses. It is also useful for dental extractions and in minor surgery for opening abscesses etc.

from 9 to 82 years and weights from 66 to 175 lb. None has shown signs of idiosyncrasy and the two deaths were quite unconnected with the anaesthesia. In two cases only was there slight cyanosis which responded to carbon dioxide and oxygen. There was usually a slight fall of blood pressure and occasional slowing of respiration. Operation was followed by apparently normal sleep lasting up to six hours.

531

## Sbrechts's Spinal Anaesthesia

R. LINDLEY (*Zbl. Chir.* March 26 1938 p. 704) discusses the problems of high spinal anaesthesia and reports favourably on Sbrechts's method after an experience of 150 varied operations on patients aged from 21 to 72. Of these operations 104 were above and forty three below the umbilicus. Three complete failures required other forms of anaesthesia. The author considers the Howard Jones hypobaric solution of percaine the best on account of its high dilution with minimum toxicity its intense and lasting effect its positive control of the height of anaesthesia and its slight effect on blood pressure due to the fact that percaine has relatively less effect on the sympathetic than other agents. He considers Sbrechts's fractionated dosage essential as it allows the correct doses to be given to ricini sensitive and ricini resistant persons thus avoiding failures or disasters due to under or over dosage. In this procedure after puncture between the third and fourth or fourth and fifth lumbar vertebrae the patient is turned on the face and injections of 5 c.c.m. of percaine are made at five minute or ten minute intervals until the required level of anaesthesia is obtained. To allow for possible errors and for the rise in level that sometimes occurs during operation the author considers that anaesthesia above the sixth dorsal segment should not be aimed at. Sbrechts's method allows of much higher dosage than would otherwise be safe. The lowest amount given in the series reported was 5 c.c.m. for amputation of a foot the highest 50 c.c.m. for duodenal ulcer. On eighteen occasions the dose exceeded 20 c.c.m. There were no cases of collapse in 21 per cent there was nausea and vomiting on the table headache occurred in six cases.

530

## Rectal Evipan Sodium

M. L. WEINSTEIN (*Surg. Gynec. Obstet.* February 1, 1938 p. 227) reviews the history of the rectal administration of anaesthetics and gives details of his experience with rectal evipan sodium. He has modified Gwathmey's dosage of 1 c.c.m. of 10 per cent solution for every 5 lb. of body weight although he considers this is within the limits of safety. Individual cases may also require modified dosage—for example robust young alcoholics need more and cachectic individuals less than the standard. Excessively fat individuals are given the dose corresponding to the normal weight for their age. The author's dosage table is as follows:

Weight	Evipan (10 per cent solution)	Preliminary Dilaudid (Hypod.)
45-60 lb.	6 c.c.m.	1-40 grain.
60-75	10 "	1-40 "
80-95	13 "	1/30 "
100-115	16 "	1/30 "
120-135	20 "	1/20 "
135-150	26 "	1/20 "
155-175	30 "	1/10 "

The injection is made with a funnel and catheter, and the patient is usually asleep in ten to twenty minutes even if the patient is only semiconscious. Amnesia is always complete. In all but minor cases supplementary anaesthesia regional local or inhalational is required. Sixty cases comprising various operations have been dealt with in this way with very satisfactory results, their ages have ranged

## Obstetrics and Gynaecology

532

## Sterility

M. RODECURT (*Zbl. Gynäk.* April 2, 1938 p. 757) quotes Schulze's findings from analysis of 1000 cases at a Berlin women's hospital that in 40-50 per cent of cases sterility is due to bilateral occlusion of the Fallopian tubes and that there is then only a 4 per cent chance of successful treatment. The necessary investigations and treatment in the remaining cases he points out, are both costly and time consuming. In point of fact the average cost of a child born as a consequence of skilled treatment of sterility has been reckoned at RM 3500. Rodecurt pleads for investigation and treatment of sterility by the private (specialist) practitioner without the necessity for authorization of the treatment and its expenses by medical officials of the insurance organizations. He analyses the records from his own practice, of 136 women seeking treatment for sterility at an average age of 29 with an average duration of sterility of two to six years. In six out of sixty four cases in which semen was examined azoospermia was found. Double tubal occlusion was proved in 19 per cent but was probably present in others also. Out of eighty patients in whom examination and treatment could be fairly satisfactorily carried out no fewer than twenty two became pregnant within six months. In nearly all these, treatment had been given for a combination of two or more of the following factors: tubal occlusion adiposity, menstrual

abnormalities adnexal inflammation trichomoniasis, cervicitis, vitamin deficiency, hormone deficiency. Laparotomy done in seven cases, led to five radical and two conservative operations being undertaken, one pregnancy followed.

### 533 Haematogenous Ovarian Infection

M FOSSEL (*Wien klin Wschr* March 25, 1938 p 357) mentions the rarity of haematogenous oophoritis but records three examples noted at Graz this year. In the first a patient with chronic otitis media died from an acute streptococcal purulent peritonitis originating from an acute purulent oophoritis on one side. In the second, lethal peritonitis arose from multiple ovarian abscesses in a patient under treatment for bilateral acute otitis. The third patient suffering from acute otitis and pneumonia had pus in an ovarian corpus haemorrhagicum. Circumstances favouring haematogenous ovarian infection were present in the three cases in that (1) the general resistance had recently been impaired by an acute epidemic influenzal infection and (2) pelvic hyperaemia had favoured bacterial invasion of the ovary—the first patient showed pelvic premenstrual congestion the second was eight months pregnant and the third was menstruating at the time of the acute pelvic symptoms.

### 534 Tetany and Osteomalacia

E KEHRER (*Z Gebirsh Gynak* 1938 116, 2 141) records the case of a female patient in whom tetany and osteomalacia were combined. He discusses the pathogenesis and treatment of both conditions. Tetany may be due to (1) hypoplasia or atrophy of the parathyroids, (2) deficiency of calcium, (3) the administration of certain poisons—for example, phosphates, oxalic acid, or sodium bicarbonate, (4) gastro-intestinal disturbance as in coeliac disease and sprue, and (5) pituitary dysfunction. Modern therapy includes the administration of Collip's parathyroid hormone, vitamin D, and large doses of calcium—10 c cm of a 20 per cent solution of calcium gluconate injected intravenously over a period of five minutes is probably the method of choice. Osteomalacia has been considered to be due to (1) hyperfunction of the ovaries, (2) hypofunction of the adrenal medulla, (3) hypofunction of the thymus, (4) thyroid dysfunction acting on the phosphorus calcium metabolism, and (5) hypofunction of the parathyroids. Treatment consists in (1) fresh air and sunlight and a well-balanced diet, (2) the administration of tricalcium phosphate, vitamins A and D, adrenal and thymus extracts and thyroxine, (3) castration by operation or x rays, and (4) operative and orthopaedic treatment of skeletal deformities. The author is of the opinion that castration, sterilization, total extirpation of the genital apparatus, and termination of pregnancy are methods which, on account of newer forms of therapy, will fall into disuse in the future.

### 535 Traumatic Prolapse

T PETRESCU (*Gynec si Obstet* November-December, 1937 p 127) describes an unusual case of acute prolapse of the uterus following rape. The patient was a nulliparous woman showing multiple stigmata of degeneration both physical and intellectual. She had a small infantile uterus, and the pouch of Douglas was abnormally deep. The prolapse occurred immediately after repeated and violent assaults by a number of drunken men and was accompanied by haemorrhage. The patient was at first able to reduce the prolapse but it recurred on the slightest exertion and rapidly became more pronounced, so that it was eventually impossible to replace the parts in position and the patient was admitted to hospital with complete procidentia. She also complained of disturbances of micturition and leucorrhoea. The prolapsed parts consisted of the cervix and extruded vagina, there was a

definite cystocele and a rectocele, which remained after the reduction of the tumour. After ten days rest and local antiseptic treatment a laparotomy was undertaken. The "isthmic hysterectomy" of Debrei, is advised by Lapcyrc, was performed and both tubes were ligated, since hysterectomy does not of course eliminate the possibility of pregnancy. Although the prolapse occurred immediately after the trauma the latter was only the accidental or determining cause, the predisposing cause being the hypoplastic condition of the parts.

## Pathology

### 536 Pneumoclonosis and Pulmonary Carcinoma

A J VORWALD and J W KARR (*Amer J Path* January 1938 p 49) claim that before dust can be assigned an aetiological significance in pulmonary carcinoma it is necessary to prove (1) that the incidence of pulmonary tumours in individuals who have for prolonged periods inhaled a particular dust is significantly higher than in the general population, and (2) that the dust in question is irritating to the pulmonary parenchyma and is actually capable of producing proliferation and carcinomatous changes in epithelial tissues. From an analysis of x ray reports on over 70 000 individuals exposed to industrial dusts, and from the necropsy reports on over 3 700 others similarly exposed they found that the incidence of pulmonary carcinoma—0.019 per cent and 0.8 per cent respectively in the two series—was lower than that in routine necropsies on the general population. Of 3,338 animals exposed for long periods to different dusts, only two guinea-pigs developed a pulmonary neoplasm in each case a benign adenoma. All the other animals failed to show irritation, hyperplasia or tumour transformation of the respiratory epithelium. The authors conclude therefore, that inhaled dusts except those containing recognized carcinogenic substances such as radium and tar, cannot in general be considered as aetiological factors in the development of pulmonary carcinoma.

### 537 Vitamin A Assay

P P SWANSON, G T STEVENSON and P M NELSON (*J Nutrit* February, 1938, p 103) have investigated the possibilities of increasing the precision of vitamin A assay. They adopted as a criterion the average standard deviation from the mean gain in weight of the rats used during the test period, the results being statistically analysed throughout. With a standard deviation of 18.1 grammes large groups of rats had to be used. As a result of analyses of factors and data involved, a "regression equation" was calculated from which it was possible to predict the gain in weight during the test period of any rat used. Using this equation, it was thus found possible to eliminate rats likely to give an erratic response to the test and so to obtain a more homogeneous group with a lower standard deviation of gains and consequent economy of work. Next the question of reducing the test period to five weeks was studied, and it was found that in the first five weeks a lower standard deviation was obtained than in the longer period, since variations in growth response occurred mostly in the later weeks of the longer period. Further when unsuitable animals were eliminated from the test by means of a new "regression equation" calculated for the five-week period, the standard deviation dropped to 12.0 grammes. Hence the authors recommend that rats giving indications (as judged from the "regression equation") in the depletion period of erratic response to the feeding of the test substance should be eliminated, and that the assay period should be reduced to five weeks. By these means greater uniformity and therefore reliability are obtained.

# Syrup **MINADDEX** *a reconstructive tonic to expedite convalescence*

PRODUCT OF THE  
GLAXO LABORATORIES

Composition of Syrup Minadex  
IRON COPPER MANGANESE  
VITAMINS A and D  
Glycerophosphates of  
CALCIUM SODIUM POTASSIUM

## POST-OPERATIVE CARE OF CHILDREN

Children are usually severely affected by surgical treatment. Haemorrhage may be serious, blood regeneration slow. The child's continued growth, the body's effort to heal and to recreate resistance, the limited capacity for nourishment—all call for the use of a reconstructive 'tonic'.

Syrup MINADDEX supplies this need—effectively and agreeably. Specially designed for children, both in composition and flavour, Minadex contains no alkaloidal stimulants. Every component contributes directly to the return of bodily health.

Prices (except in Eire) 6-oz bottles, 2 6, 12-oz, 4 6,  
So-oz winchesters, 22 6. Less usual professional discount.

# Endocrine Therapy . . .

FOR many years the research staff of Parke, Davis & Co. has devoted special study to the perfection of the processes of manufacture of gland preparations in order that these substances may be presented in active form for therapeutic use.

ADRENALIN, the first hormone to be isolated in pure crystalline condition, was marketed by Parke, Davis & Company in 1901, and 'PITUITRIN,' the first extract of posterior pituitary gland, was introduced in 1908. Two active principles, 'PITOCIN' and 'PITRESSIN' were separated from 'Pituitrin' in the P, D & Co. Research Laboratories in 1927.

Studies of the anterior lobe of the pituitary gland led to the introduction of a solution of the growth hormone, ANTUITRIN GROWTH, and ANTUITRIN 'S,' a solution containing the anterior pituitary-like sex hormone. Other endocrine preparations manufactured in the Parke-Davis Laboratories include ESCHATEIN, the original preparation of the suprarenal cortex hormone, THEELIN (keto-hydrocortisone), THEELOI (tri-hydrocortisone, for oral administration), PAROIDIN, a solution of the parathyroid hormone, and LIPO-LUTIN, a solution of the corpus luteum hormone, etc.

Nearly forty years' experience in research work enables Parke, Davis & Co. to control the activity of those endocrine preparations that can be standardized by chemical or biological assay and physicians may, therefore, have absolute confidence in the specification 'P, D & Co.' on prescriptions for endocrine products.

## KOROMEX METHOD

The Koromex Occlusive Diaphragm is made in a range of sizes to fit each individual patient, pure latex rubber pessaries. Light and comfortable, practically infelt. Two-year durability guaranteed. Practitioners and birth control clinics, for more certain protection prefer to use the perfect fitting Koromex Diaphragm with

## KOROMEX VAGINAL JELLY

Stainless and prolonged effective spermicide. The carefully gauged viscosity of Koromex Jelly affords the all-important mechanical block. No toxicity or irritation makes the diaphragms easier to insert.

Advise the Koromex Method. Your patient will be grateful.

A sample of Koromex Jelly will be sent on application to medical practitioners, also a booklet, the Physician's Guide, on the technique of fitting the Occlusive Koromex Diaphragm. No charge. Write to

## The Highest Record of PROVEN SUCCESS in Contraceptives

- Evidence of the high degree of efficacy of the Koromex Method is based upon the experience of 234 clinics—140 hospitals—over 50,000 physicians

## THE KOROMEX METHOD KOROMEX DIAPHRAGM + KOROMEX JELLY

- The Koromex Diaphragm appears on the National Birth Control Association's approved list with seven Prentif products, including Condoms, Sheaths, Jellies and Suppositories. Price list and samples on request.

# THE NEWEST IDEA IN HEARING AIDS

*The most beneficial and  
the essence of convenience*

As a sufferer from deafness for many years and one who has tried practically every instrument evolved, writes T. C. V. Littlehampton: "I find that the V.P. Maxade is definitely the most beneficial and is the essence of convenience."

Unobtrusive and reliable, the new V.P. Maxade consists of three compact units (each as easy to conceal in the clothing, or handbag as a cigarette case). It comprises a 3 valve amplifier and sensitive crystal microphone for either bone or air conduction hearing, miniature or direct type earpieces and combines the important advantage of invisibility

with the efficiency only possible in an electrical valve instrument.

Maxade is entered upon the Approved List of the National Institute for the Deaf and consistently used and prescribed by the principal hospitals and clinics. A Model will gladly be lent for free clinical test. Details of the V.P. Model and other reasonably priced Maxade Models from Mr. W. Scott Worthington, I.R.S.A. PHOTO SCOTT CO. LTD. 77 City Road F.C.I. (Acoustical Engineers since 1919). On view at the Empire Exhibition (Lancashire—Hall of Industry (North Section) Stand No. T 106.

# "CURTIS"

ABDOMINAL  
SUPPORT  
NO. 1

RT 1

*for Steady, Permanent Support*

The Curtis Model No 1 Support has many advantages over the old type abdominal belt. It is light in weight and is scientifically designed to give maximum support upwards and backwards to the lower abdomen with minimum constriction. The hips are given complete freedom of movement and the support itself is extremely comfortable. Leading London Hospitals and the medical profession unhesitatingly prescribe Curtis Model No 1—the most efficient support obtainable.

# UNIVERSITY OF LONDON

## BRITISH POSTGRADUATE MEDICAL SCHOOL (DEPARTMENT OF PATHOLOGY)

### DIPLOMA IN CLINICAL PATHOLOGY

A COURSE OF STUDY in the academic year 1938-9 will be held for this Diploma commencing on October 3rd 1938. The Course will occupy twelve calendar months. The subjects embraced will be—

HAEMATOLOGY AND CLINICAL PATHOLOGY      BACTERIOLOGY  
PATHOLOGICAL CHEMISTRY      MORBID ANATOMY AND HISTOLOGY

The Course will commence with Haematology and Clinical Pathology which will occupy about 12 weeks and will be followed by the Course in Pathological Chemistry which will occupy about the same time. The Courses in Bacteriology and Morbid Anatomy and Histology will run concurrently and occupy about 12 months. For the last three months of the Course students will be occupied in the practice of routine work in the Laboratories of the Department and in revision work. The number of places in the Course is limited and students will be selected shortly before the Course is due to commence.

Fee forty guineas.

In addition to the full Course it will probably be possible to enrol a limited number of students for the subjects of Pathological Chemistry and Clinical Pathology and Haematology separately. The Course in each subject lasting about six weeks. Fee for either Course nine guineas.

Further particulars may be obtained from the Dean, British Postgraduate Medical School, Ducare Road, Shepherd's Bush, London W 12.

## FACULTY OF MEDICAL SCIENCE

The Medical Faculty at this College of the University gives instruction in the subjects of Medical Science for all the usual Pre-Medical and Intermediate Examinations in Medicine, Surgery and Dentistry. Through the four associated hospitals, Students of the College have clinical facilities of over 1,000 beds.

The Medical Faculty of the College provides a general University education in touch with other Faculties, classes of which medical students are permitted to attend. There are many College societies, clubs and functions in which students of all Faculties have opportunity of meeting each other. The College has an excellent athletic ground at Mitcham with a new and well equipped pavilion.

The First Year subjects are taught in the three Departments of the Faculty of Science and those of the Second and Third Years in the new Medical Department. This includes the Hablestree Department of Anatomy and an extension to the Department of Physiology recently completed at a cost of £40,000. These new buildings and those of recent years provide the College with a completely new and modern Medical Department which embodies the newest ideas in laboratory construction and equipment.

Valuable scholarships and prizes are awarded on the results of examinations held annually.

The Hostel for men students (The Platanes, Chipping Hill, S.E.5) contains accommodation for 80 students. The Hostel for women students is at 55 Queenborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean of the Medical Faculty or to

## ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from fully qualified male registered Medical Practitioners (unmarried) for the post of Assistant Resident Medical Officer at Southlands Hospital, Shoreham by Sea, near Brighton. The appointment is for one year. Salary £300 per annum with board, residence and laundry. Preference will be given to candidates who have had special experience in obstetrics and gynaecology. The Hospital (350 beds) is a general hospital under the administration of the East Sussex County Council. The duties of the post are mainly concerned with obstetrical cases (40 maternity beds) but there are general duties in addition.

Application should be made on a form obtainable from the undersigned at the County Hall, Lewes, and must be returned to him by Saturday, June 25th 1938.

HUGH J. T. McILVEEN  
County Hall, Lewes Clerk of the County Council  
June 3rd 1938

## HOLLAND (LINCOLNSHIRE) COUNTY COUNCIL

ASSISTANT MEDICAL OFFICER OF HEALTH  
(Male)

Applications are invited from duly qualified and registered medical practitioners (under 40 years of age) for the above appointment.

The salary will be £600 per annum rising by annual increments of £25 to £700 per annum.

The duties of the post include school medical inspections, the carrying out of work under the Maternity and Child Welfare and Tuberculosis schemes and such other duties as may be required by the Council.

The person appointed will devote the whole of his time to the duties of the office, act under the direction and supervision of the County Medical Officer and reside in such part of the district as may be required.

Applications on the prescribed form obtainable from the undersigned accompanied by copies of not more than three testimonials must be addressed to the County Medical Officer of Health, County Hall, Boston, Lincs. and received by him not later than June 25th 1938.

W. G. ROOTH  
County Medical Officer of Health  
County Hall, Boston  
June 6th 1938

# INDIAN MEDICAL SERVICE

## RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age and who are registered under the Medical Acts in Great Britain and Northern Ireland are eligible to apply.

### CAREERS

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, perialist and research work. At the beginning of his career an officer is employed on the military side which has medical posts in the Indian Army. Promotion is on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes, to specialist (for example, in health and bacteriological) services, to research posts and to professorships at the Medical Schools.

### RATES OF PAY

Years of Service	Rank	Basic Pay Rs per mensem	Overseas Pay £ per mth	Total £ per annum
1	Lieutenant	450	15	55
2	Captain	500	25	75
3	"	550	25	75
4	"	600	25	95
5	"	650	25	95
6	"	700	30	100
7	"	750	30	100
8	"	800	30	100
9	"	850	35	105
10	"	900	35	110
11	Major	950	35	110
12	"	1000	40	120
13	"	1050	40	120
14	"	1100	40	120
15	"	1150	40	120
16	"	1200	40	120
17	"	1250	40	120
18	"	1300	40	120
19	"	1350	40	120
20	"	1400	40	120
21	Lieut. Col	1450	40	120
22	"	1500	40	120
23	"	1550	40	120
24	"	1600	40	120
25	"	1650	40	120

(1) The rate is at present stabilized at a rate equivalent to 1s. 6d. (2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1,400 per mensem (basic) plus £40 per month overseas pay.

Extra—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side and may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments in officers in both branches of the Service.

### ANTEDATES IN COMMISSION

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized

hospitals may be seconded in those posts for a period. The maximum period of antedate, secondment or antedate and secondment combined admissible under this paragraph is limited to 18 months.

### OUTFIT ALLOWANCE

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

### PRIVATE PRACTICE

With the exception of Administrative Officers, military or civil and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

### LEAVE

Leave can be taken at reasonable intervals and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed twelve months in all during an officer's service may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave study allowance at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe and £1 10s. a day in the United States of America and Canada is granted to an officer in addition to ordinary rates of leave pay.

### PENSIONS

The rates of pensions are as follows —	Per annum
After 17 years' service for pension	£372 0s.
18 "	£400 0s.
19 "	£428 0s.
20 "	£465 0s.
21 "	£502 0s.
22 "	£539 10s.
23 "	£576 10s.
24 "	£614 0s.
25 "	£651 0s.
26 "	£697 10s.
27 "	£744 0s.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

### PASSAGES

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India subject to the payment of messin charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

### INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. The Selection Committee will meet at the India Office about July 26th next, and the selected candidates unless seconded for hospital appointments will be required to join a course of instruction commencing about September 1st prior to sailing for India in December 1938. Applications should reach the India Office as soon as possible.

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in September, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployment or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post-graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st August, 1938.

## WOLVERHAMPTON EDUCATION COMMITTEE

Applications invited for appointment as SENIOR ASSISTANT SCHOOL MEDICAL OFFICER (full time). Salary £700 per annum rising by two annual increments of £25 and thence by two further annual increments of £50 to a maximum of £850.

Applicants should have had experience in the practice of their profession subsequent to qualification and should hold a Degree or Diploma in Public Health in addition to full medical qualifications. Preference will be given for experience in the School Medical Service and of diseases of children. Practical experience in certification under the Mental Deficiency and other Acts and a knowledge of Special Schools requirements will be an additional qualification.

The person appointed will be on the staff of the Education Committee functioning through the Director of Education and the Medical Officer of Health who is also School Medical Officer.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922.

Further particulars and conditions may be obtained on sending stamped addressed foolscap envelope to the undersigned to whom completed applications must be sent by July 2nd.

Education Officer F A WARREN  
North Street  
Wolverhampton  
June 1938

## SUDAN MEDICAL SERVICE

Applications are invited for the post of JUNIOR BRITISH LABORATORY ASSISTANT male, married in the Strick Medical Research Laboratories Khartoum to commence duty on November 15th 1938.

The salary commences at £E 324 or £E 360 (£E -£1 0s 6d) according to age and qualifications rising by two three yearly increments to £E 780 after eighteen or twenty years depending on the initial rate. The appointment carries prospects of pensionable service after five years' service. A free passage to the Sudan will be provided.

Candidates should be between 22 and 30 years of age and should hold the Laboratory Assistant's Diploma of Bacteriological Technique and preferably have some experience in Clinical pathology.

Application stating age, qualifications and copies of testimonials should be sent to Dr H C SQUIBB 93 Harley Street W 1.

## CITY AND COUNTY OF NEWCASTLE UPON TYNE

The Health Committee invite applications from duly qualified and registered Medical Practitioners for the appointment of SENIOR CHILD WELFARE OFFICER.

Salary £750 per annum rising by three annual increments of £50 and one of £37 10s to £937 10s per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the successful candidate will be required to pass the necessary medical examination.

The officer appointed will not be concerned with the administration of the City's Maternity Scheme but will be required to devote his or her attention entirely to the supervision of the Child Welfare Services.

Applicants for the appointment  
(1) Must have been qualified at least three years.  
(2) Must have experience in child welfare work.  
(3) Must have held a resident appointment in a recognized teaching children's hospital.

The possession of the Diploma in Child Health granted jointly by the Royal College of Physicians and the Royal College of Surgeons will be regarded as an additional qualification.

The City's Child Welfare Scheme is organized in such a way as to provide special opportunities for research work in sociological and clinical problems. Candidates either directly or indirectly will be considered a disqualification.

Further details of the appointment and special application forms can be obtained from the Medical Officer of Health Health Department Town Hall Newcastle upon Tyne 1 to whom all applications should be submitted not later than Saturday June 25th 1938.

# LACIDAC

REGD

In spite of advancing knowledge of Infant Dietary, there is still a high mortality rate amongst Infants from affections of the alimentary tract—particularly during the warmer summer months.

Lactic Acid milks are acknowledged to be of great value in these cases and Lacidac presents a standardised and easy form which can be prescribed with confidence.

Clinical samples and literature will be gladly sent on to any member of the Medical Profession.

In acting as an executor or trustee, the Westminster Bank aims at putting itself in the position of a private trustee. It is therefore its practice to employ the family solicitor, if there is one, or any other solicitor the client may name, by such means the Bank succeeds in combining domestic tradition with business efficiency. A book showing the advantages of corporate executorship and the terms of appointment may be had at any branch or at the branch situated in BMA House, Tavistock Square, W C 1

## HEARING AID-

the obvious move is to send him to a firm offering facilities for testing ALL TYPES of reliable aids, and who will, at the same time, consider it their personal obligation to give both doctor and patient complete satisfaction

Allen & Hanburys' Acoustic Department has a reputation for giving every consideration to the personal problems of deaf patients when some form of artificial aid becomes necessary. Audiometers tests are made, a home trial arranged, and a full report submitted to the doctor concerned. Once the aid has been supplied, contact with the patient is maintained until all the small difficulties experienced in the early stages of use are overcome. Provision is also made for adjustments to meet any change in aural conditions at a later date.

In short, a comprehensive after-service is available to each patient, ensuring that not only his immediate but also his future needs in relation to a hearing aid are safeguarded in an ethical manner.

# In the most unexpected places

The illustration below shows a retailer's cottage premises in the little village of Cockfield, Suffolk. Player's Navy Cut Cigarettes can be purchased here as in many similar picturesque and remote spots all over the country.

Numerous letters from smokers tell of pleasure in finding their favourite "Player's" on sale here, there and everywhere... in the most unexpected place... The vast demand which makes this possible also guarantees their unfailing freshness, and is promptly supplied by smokers themselves that there is no better Cigarette at 10 for 6d.

Remember also whatever your taste, you can please yourself by choosing "Medium" or "Mild" brands - Cork tipped or Plain.

*panties*  
designed by J Roussel

## The modern garment for health and beauty

Women will always seek beauty of figure. In the Panties designed by Roussel they have a garment that gives a fashionable line and one that their medical adviser can approve. Roussel Panties are woven to give support to the lower abdomen without dangerous pressure on the abdominal organs. Being woven to measure they do not restrict thighs or waist. The special elastic tricot from which they are woven exerts a gentle massaging action which stimulates circulation, assists in dispersing fat and encourages the natural eliminative functions. If you would like to know more about Roussel Panties and other figure control creations designed by Roussel, please phone or write for a copy of our beautifully illustrated Catalogue. Prices from 2 Guineas. A reduction of 2s. in the £ is made on purchases for personal use by members of the Medical Profession. Write to Dept ME

## MILTON AS A DOUCHE

Patients often ask for advice on a suitable antiseptic. In the many cases where a douche is indicated, Milton is particularly suitable.

- 1 It is alkaline with a pH of about 10, due to sodium carbonate and not to caustic soda. On dilution it forms a mildly alkaline solution which corrects any acidity, but does not harm mucous membranes.
- 2 Even at considerable dilutions, it is still a hypertonic solution.
- 3 It is miscible with mucus and pus and dissolves semi-solid protein matter, thus acting as a cleansing agent.
- 4 As will be readily appreciated from its content of 1 per cent of hypochlorite, it has a powerful germicidal action on any micro-organisms likely to be found in the vagina or uterus. For *B. coli*, for example, it has a R.W. Coefficient of 2.12.
- 5 It is a deodorant with immediate action, destroying the organic gases by oxidation.

Owing to its reasonable price—Milton is sold by all chemists from 6d. per bottle upwards—it can be recommended even when expense is a main consideration.

A copy of the Pease Laboratories' Report on Milton, some notes on the value of Milton in Gynaecology, and a generous professional sample bottle of Milton will be sent to any medical practitioner.

MILTON PROPRIETARY LTD.,  
JOHN MILTON HOUSE, LONDON, N 7

# MEDICAL FACTS ABOUT TEA

---

In order to remove certain popular misconceptions about the chemical properties of Tea thorough clinical and laboratory investigations have been conducted. The following is a brief summary of the main results of these investigations —

- (a) Tea as normally drunk is harmless and has no ill effects whatever on the human body. The amount of caffeine and tea tannin in tea is pharmacologically small.
- (b) Tea tannin is a different substance from the tannic acid of the Pharmacopœia, which is a Pyrogallie tannin, and the two should not be confused.
- (c) Clinical experiments have shown that the action of tea tannin is very much milder than that of tannic acid, and the different composition of the two tannins is proved by the fact that the tannic acid of the Pharmacopœia is about 25 times stronger as an acid than tea tannin.
- (d) Many common beverages besides tea contain similar tannins.
- (e) A thorough investigation reported in "The Analyst" (1936, LXI, 310) could find no tea on the market which was free from tannin. If there were any such teas, they would be almost entirely tasteless.

## FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research acetyl salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has however caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that Alasil definitely solves the problem of administering acetyl salicylic acid in an effective form being free from the risk of irritating the stomach or bowels or of causing general reactions.

*A supply for clinical trial with full descriptive literature sent free on request*

In 'Alasil' the desirable therapeutic effects of acetyl salicylic acid are well exhibited by its calcium acetyl salicylate moiety while the presence of Alacol (Colloidal Hydroxide of Aluminium) a powerful gastric sedative and antacid obviates any tendency to gastric irritation. The superior absorbability of Alasil over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. 'Alasil' can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

# ASCORBIC ACID B.D.H.

(VITAMIN C)

During all pyrexial conditions the body requirements of Vitamin C are raised considerably above the normal. Modern opinion favours the administration of large doses of Vitamin C to meet such increased demands. The B.D.H. range of preparations of Ascorbic Acid (Vitamin C) includes forms suitable for administration in all such cases, the requirements of which cannot be adequately met by an increased dietary intake.

## B.D.H. SEX HORMONE PREPARATIONS

Complete endocrine therapy in obstetrics and gynaecology is possible with B D H Sex Hormone Preparations

### *For Ovarian Stimulation Therapy*

#### SEROGAN

Serogan is obtained from the serum of pregnant mares, its action upon the ovary is mainly that of follicle stimulation

#### GONAN

Gonan is the gonadotropic substance from the urine of pregnancy, its effect upon the ovary is primarily luteinising

### *For Ovarian Substitution Therapy*

#### OESTROFORM

The oestrogenic hormone in accurately-standardised form

#### PROGESTIN B D H

The standardised corpus luteum hormone

MORE and more clinical information is becoming available concerning methods of application of these hormone products in the various indications for their use, this information is summarised in a recently-published booklet entitled 'The Therapeutic Application of the B D H Sex Hormones in Gynaecology and Obstetrics', a copy of which will be sent willingly to any physician on request

# 'AMYTAL'

BRAND

*Iso-amyl Ethyl Barbituric Acid*

## FOR SEDATION AND HYPNOSIS

● The tranquil sleep of children is always the envy of less fortunate adults to whom at times this boon is denied because of sickness or other conditions which upset the psychic or emotional equilibrium

'Amytal' supplies the relaxation and sleep which are essential to recuperation of vital forces. It may be prescribed wherever there is need to combat insomnia, restlessness, or apprehension. A noteworthy margin of safety is characteristic of 'Amytal,' and since destruction of the hypnotic within the body appears to be accomplished rapidly there is little tendency to unwelcome side-reactions or after-depression.

'Amytal' is supplied in  $\frac{1}{2}$  gram,  $\frac{3}{4}$  gram and 1 $\frac{1}{2}$  gram tablets in bottles of 40 and 500

*Serenol* is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system, and on this knowledge SERENOL is based. It is thus a biological, not a symptomatic, sedative, and, unlike many other sedatives, has not a direct depressant action on the cortical cerebral centres.

*Serenol* is indicated in conditions of anxiety and general irritability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so called nervous palpitations of the heart, etc.

*Serenol* is given in the following dosage. For mild cases one to two dessertspoonsful on retiring. For more severe cases one dessertspoonful at 10 a.m., one dessertspoonful at 4 p.m. and two dessertspoonsful on retiring.

*Serenol*, being a biological sedative containing no barbiturate, is not habit forming.

## MIST. DAMIANÆ CO.

(HEWLETT'S)

MIST DAMIANÆ CO (Hewlett's) will be found to possess all the properties of Damiana viz —its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay are far more prevalent at the present day than ever before. The causes are numerous and complex but perhaps the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anaemia is therefore one of the most general complaints in modern life. Not only is it found among the professional literary men but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power Mist. Damianæ Co (Hewlett's) is a powerful remedy relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion especially in the nervous depression following influenza.

## WHAT ARE THE ADVANTAGES OF BRAN AS A LAXATIVE?

**C**LINICAL TESTS show that, in the treatment of common constipation by increasing the intake of "bulk" in the diet, bran in the pleasant form of Kellogg's All-Bran gives the most favourable results.

The advantages of All-Bran as a laxative food may be summarized briefly as follows: (1) The "bulk" in All-Bran is absolutely non-irritant but does not break down as readily as does the bulk matter of fruits and vegetables, and is therefore more effective. (2) Its continued use does not reduce its laxative effect. (3) It is a good source of Vitamin B<sub>1</sub> and also contains iron. (4) Being a food rather than a medicine, the "psychological" effect of All-Bran is helpful: patients appreciate the fact that it is a pleasant, "natural" treatment which need not interfere with their normal mode of life.

Kellogg's All-Bran may with advantage be prescribed in all cases where an increase in the amount

of "bulk" in the diet is indicated. Within the body, it absorbs water and softens like a sponge. This water-softened mass gently but effectively aids elimination — gently exercises the digestive tract. Eaten regularly, All-Bran promotes thorough evacuation of the bowel contents without strain on the internal organs.

All-Bran may be served as a cereal with milk or cream, or cooked into appetising scones, bread, etc. It may also be taken in combination with other cereals or sprinkled over salads and other foods. To assure maximum effectiveness, plenty of fluids should be taken, preferably between meals. All-Bran is obtainable from all reliable grocers. A packet will be sent free on request to any qualified practitioner. Inquiries should be addressed to Kellogg Company of Great Britain Ltd., Strerford, Manchester.

The illustration is divided into three parts. The top left shows a large, fluffy pile of All-Bran cereal. The top right shows a tall glass of water with a small amount of All-Bran being added, creating a dark, textured mass. The bottom left shows a bowl of All-Bran cereal with milk, next to a packet of All-Bran cereal.

All Bran is not unlike a sponge in its absorbency and softness and to some extent also its effect on the intestines resembles the cleansing action of a water softened sponge. The amazing softness and absorbency of All Bran is strikingly shown when a small quantity is dropped into a tumbler and water added. It will at once be seen how readily All Bran takes up the water forming a large smooth mass.

# Allenburys Orange Juice

CONCENTRATED SWEETENED

Supplies a potent source of the anti-scorbutic vitamin C in a form convenient for infant feeding and other purposes

It is equivalent to about four times as much fresh orange juice and retains its full activity for a long period

Employed with advantage in all cases in which fresh orange juice is used

May be taken by children and adults in the form of a delightful drink by diluting with about ten times its volume of plain or aerated water or milk

In bottles, 2/3 each

# RAMLÖSA

### 50 YEARS' REPUTATION FOR MEDICINAL AND TABLE USE

This famous natural mineral water is bottled at the source and slightly aerated with pure Carbonic Acid. The characteristics of "Ramlosa" are a relatively high Sodium Carbonate content in combination with an uncommonly low content of Calcium and Magnesium Salts (practically none) and a virtually complete absence of iron. "Ramlosa," in consequence, avoids the fault of certain natural mineral waters which upset the digestion by partially neutralising the hydrochloric acid in the gastric juice. "Ramlosa" considerably increases the amount of urine and is therefore indicated in the treatment of diabetes, gout, kidney troubles and other metabolic disorders, as well as in rheumatism and in conditions where a large supply of fluid is of importance as a mild form of irritant physical therapy.

# VITAMIN B<sub>1</sub> IN FOODS

*Biochemical J, 1935, and other sources*

*The figures represent International Units per ounce*

*Laboratory reports on Bemax; and a clinical sample for personal trial sent on request*  
 The Bemax Laboratories (Dept B 63), 23, Upper Mall, London, W 6

## "Vitamin B<sub>1</sub> deficiency an outstanding fault in the diet of many millions of people"

*(B M J, 16 Oct, 1937 p 753)*

The reduction in Vitamin B<sub>1</sub> intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent, and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B<sub>1</sub> activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B<sub>1</sub> supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B<sub>1</sub>, significant quantities of Vitamin B<sub>2</sub> and B<sub>6</sub>, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B<sub>1</sub> activity with no addition whatsoever. Clinical sample and literature on request. The Bemax Laboratories, 23, Upper Mall, Hammersmith, W 6.

## Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

# Nervous Disorders

'SANATOGEN' exhibits Phosphorus and Albumin *in a form readily assimilated by the organism*. As a deficiency of these elements is invariably associated with cases of Nervous Disorders, 'SANATOGEN' by making good this deficiency exerts a restorative and revitalising effect on the debilitated nerves. It is an axiom that both general and local diseases of the nervous system can be influenced for good by careful attention to the conditions of nutrition in the individual cases. 'SANATOGEN' is definitely indicated, for in addition to being readily absorbed it also increases the absorption of other foods and increases their nutritive value.

An article on *The Treatment of Neurasthenia and Allied Conditions of the Nervous System*, by M.D., D.P.H., states —

"Amongst the many preparations I have tried, I find Sanatogen reaches more nearly the ideal than any other. Of its ready and complete absorption there is no doubt. Its food value is best observed clinically, and the cases which I have included in this paper amply show that in this respect it is of the highest value.

"The combination of casein with glycerophosphate of sodium makes Sanatogen peculiarly useful for cases of neurasthenia; the well known properties of the glycerophosphate salts in nervous diseases of the neurasthenia type needing no further comment.

"Sanatogen is a valuable preparation in those forms of neuralgia or neuritis not associated with the presence of any local irritant.

"The value of Sanatogen as an aid to digestion as well as a food is well illustrated by the following —

Case V H.C., Aet 34 years, suffering from marked dyspepsia, loss of appetite, and had lost 10½ lbs in weight during his two months absence. He was ordered two teaspoonsful of Sanatogen thrice daily, and ordinary diet. At the end of a week his indigestion had entirely gone, his appetite was normal, and he had already increased 2½ lbs in weight.

Sold by all chemists  
price 2/3 to 19/9

DOSAGE For children and adults two teaspoonsful three times daily or according to circumstances. For infants ½ teaspoonful added to each bottle feed.

## Tetanus Antitoxin

Clinical and experimental observations have proved the value of tetanus antitoxin when used prophylactically. A dose of 3,000 to 6,000 International units should, therefore, be administered in all cases where there is a possibility of infection with *B. tetani*. If an operation is considered necessary the antitoxin should be given 3 to 6 hours before any attempt is made to clean the wound.

If any manifestations of tetanus are observed energetic specific treatment should be commenced immediately. A dose of 32,000 or 40,000 International units should be injected intrathecally, and the same or in even greater amount should be given intramuscularly. Further doses depend upon the patient's condition and when this improves the amount of antitoxin administered may be gradually diminished.

*Professor of Medicine University of London Director of the Department of Medicine  
British Postgraduate Medical School*

### LECTURE III

#### Pharmacology and Therapeutics of Prostigmin

In the first lecture I described the action of physostigmine in increasing and prolonging the effects of stimulation of cholinergic nerves of the muscarine type and the effects of injected acetylcholine and explained that this action is due to the inhibition of the choline esterase present in the tissues and blood so that the hydrolysis and destruction of acetylcholine is delayed. In 1931 Aeschlimann and Reinert showed that a synthetic analogue of physostigmine, the dimethyl carbamic ester of 3-oxophenyl trimethyl ammonium methyl sulphate, has pharmacological actions similar to those of physostigmine. This substance known as prostigmin stimulates intestinal peristalsis as powerfully as physostigmine but has less effect on the heart and circulation. Ammon (1933) showed that prostigmin inhibits choline esterase as does physostigmine and McGeorge (1937) working in my department showed that it not only reduced the esterase activity of normal serum but that the activity was restored when the prostigmin was removed by dialysis acting in this respect in the same way as physostigmine (Matthes 1930). It is probable therefore that the actions of prostigmin are due to this inhibition of choline esterase and that the effects of its administration are due mainly to the potentiation of acetylcholine effects occurring normally in the body.

#### Investigation of its Therapeutic Action

Prostigmin was recommended by the manufacturers for the aporetic use as an intestinal stimulant in cases of post-operative intestinal atony and a number of favourable reports have been published (Weigand 1931, Leiner 1931, Tourneux, Petel and Gouzi 1931, Kottlors 1932, David 1935, Begg 1937 and Harger and Wilkey 1938). In 1933 at the request of the Therapeutic Trials Committee of the Medical Research Council an investigation of its therapeutic action was carried out in this country on the prostigmin supplied by Roche Products Limited. The action of the drug was studied on subjects with normal gastro-intestinal functions following barium meals and on patients with post-operative intestinal distension and other abnormalities (Carmichael, Fraser, McKelvey and Wilkie 1934). When given by subcutaneous or intramuscular

injection in doses of 0.5 to 1.5 mg increased activity in the movements of the colon was observed and in cases of gaseous distension abdominal pains and rumblings occurred in from ten to twenty minutes following the injection and continued for thirty minutes but to obtain a satisfactory passage of flatus it was necessary to give an enema in addition. With these doses slight reduction in pulse rate and blood pressure occurred: one patient showed sweating and twitching of the muscles of the trunk and limbs was observed in two patients.

#### EFFECT OF INTRAMUSCULAR INJECTION

Following the report in 1935 by Dr Mary Walker that prostigmin was more satisfactory than physostigmine in the treatment of myasthenia gravis and that it is necessary to employ it in considerably larger doses (2.5 to 5 mg) than had been advocated for intestinal distension I have

FIG 10

observed with the help of F W Gordon and C R Baxter the effect of doses up to 2.5 mg by intramuscular injection in twelve hospital patients. The effects vary considerably from subject to subject. A typical response is seen in Fig 10. The patient had essential hypertension but was free from symptoms on moderate exertion. Reactions similar to those seen following the injection of choline esters occur but the onset is more gradual, there is no rise of pulse rate, the fall of blood pressure is slight and in

accompanied by twitching of muscles rarely noted with doryl is a striking feature. This usually begins in the orbicularis palpebrarum, the patient complaining of a stiffness around the eyes and it may spread to the pectoral muscles, the muscles of the abdominal wall, the legs, the neck, and the shoulder girdle. These twitchings are brief contractions involving part of a muscle at a time, and often powerful enough to cause movements of tendons and the patient may be conscious of them. The whole of a muscle is rarely involved in one twitch but the contraction commonly involves more muscle fibres than is usual in the fibrillary tremors of progressive muscular atrophy. With the appearance of the twitching of the muscles there is an increase in the tendon reflexes. The effects begin to pass off in about thirty minutes after the injection, and have usually

FIG 11

FIG 12

disappeared in forty minutes or an hour and not infrequently the subject feels drowsy and may go to sleep at this time. Atropine abolishes the parasympathetic effects but not the twitching of the voluntary muscles. Following 1 mg. in the same subject no symptoms were noted apart from a feeling of warmth and slight sweating fifteen to twenty minutes after the injection. A dose of 1 mg., however, produced a striking increase of visible peristalsis in a patient with megacolon (Fig. 11) but no relaxation of the sphincter and no improvement in the size of the colon or in its functions were observed at the end of four weeks during which he received three injections daily of 1 mg. A desire to defecate is usually experienced twenty minutes or an hour after a dose of 1 or 2.5 mg. more than the larger dose of 5 or 10 mg. commonly no defecation occurs, the stool flatus is passed and the bladder emptied (Fig. 12).

It would appear, therefore, that by means of prostigmin the normal cholinergic nervous effects in man are increased—both the muscarine-like parasympathetic effects and the nicotine-like effects on voluntary muscle. Doubtless physostigmine would have the same action but in doses sufficient to produce the effects on voluntary muscle it causes in man such severe cardiovascular inhibition with vomiting, headache, and general malaise that it is unsatisfactory for therapeutic purposes or for making clinical observations.

#### ITS VALUE IN INTESTINAL DISTENSION AND ATONY

Apart from the use of prostigmin in myasthenia gravis, which will be considered later, its therapeutic value has been established so far only in the treatment of intestinal distension and atony. For this it is probably less reliable than doryl and mechohol, but with doses usually effective (0.5 to 1 mg. by subcutaneous or intramuscular injection) undesirable effects on the cardiovascular system and, so, eating are much less. Since it acts by exaggerating normal mechanisms it may well be found to have therapeutic value in increasing reflex responses, such as carotid sinus and oculo-cardiac reflexes, but at present there is not enough evidence to justify any conclusions.

Laurent and Waller (1936) showed that all the actions of prostigmin can be obtained by oral administration, but that to produce comparable results much larger doses are required than by injection. They found that in cases of myasthenia gravis 25 to 30 mg. by the mouth gave a result similar to that following 0.5 mg. by injection and that 50 mg. by the mouth was comparable in its effects to 1 mg. by injection. Other authors have confirmed this in cases of myasthenia gravis, and Mitchell (1937) has noted the production of the usual parasympathetic effects following the oral administration of 90 mg. daily in from three to six divided doses.

Goodman and Bruckner (1937) record that two and three-quarter hours after an oral dose of 45 mg. a healthy subject while walking home experienced a train of symptoms that were severe and alarming, including those of parasympathetic stimulation and twitching of voluntary muscles. The authors suggest that the exertion of walking produced acetylcholine, which was protected from hydrolysis by the prostigmin, was carried throughout the body and produced the symptoms peripherally. Atropine abolished the alarming symptoms, and no similar occurrence has been recorded following oral administration.

#### Myasthenia Gravis

Because of the resemblance of the condition of the voluntary muscles in myasthenia gravis to curare poisoning and the known antagonism between physostigmine and curare, Dr. Mary Walker tried physostigmine in the treatment of myasthenia gravis. A striking and dramatic effect was seen, the muscle weakness and fatigue being temporarily abolished (Walker, 1934). She later reported that prostigmin was as efficacious and that full therapeutic results could be obtained without the undesirable toxic effects that occurred with effective doses of physostigmine (Walker, 1935). Since then a number of reports have been published confirming this use of prostigmin whether given by injection or by the mouth (Pritchard 1935, Laurent, 1925, Lindsley, 1935, Minaki and Sioris 1926, Wade 1926, Marinisco, Sager and Krenn 1926, Cooke and Pastore, 1936, Winkelman and Moore 1937, Mitchell 1937, Riven and Wilson 1937, Harvey and Whitchell 1937, Vies, Mitchell and Sen 1937, Kennedy and Wolf, 1937, 1938, Vies and

Shivab (1935) and Harvey and Whitchell (1937b) regard the response to prostigmin as so specific as to have diagnostic value.

The explanation of this striking and specific effect of prostigmin in myasthenia gravis may be expected to throw light on the pathology of the disease. Two possible explanations have been suggested in terms of acetylcholine transmission. (1) There may be a disturbance of the normal balance between acetylcholine production and its destruction by choline esterase—either a defective production of acetylcholine or an abnormally rapid destruction of acetylcholine by esterase so that a deficiency of the transmitter or the effect of the nervous impulse results—and prostigmin by inhibiting the esterase restores the balance. (2) there may be a curare like substance present in myasthenia gravis that interferes with the transmission by acetylcholine to the muscle and is antagonized by prostigmin which potentiates the transmitter.

There is good evidence that the esterase content of the serum is not increased. McGeorge (1937) estimated the esterase activity of the serum of 132 hospital patients including three with myasthenia gravis. He found a wide range but was unable to correlate the activity with any disease process or other abnormality. The esterase contents of the serums from the three cases of myasthenia gravis were well within the range found by him in the other cases. Siedman and Russell (1937) estimated the esterase in whole blood serum and corpuscles from twelve cases of myasthenia gravis ten other patients and five normal subjects. They concluded that the serum esterase was lower in myasthenia gravis than the average of normal persons but that the esterase in the corpuscles was normal. Pichler (1937) also found the average activity in the blood from seven cases of myasthenia gravis lower than from fourteen normal subjects. As McGeorge pointed out it is possible that the esterase activity at the neuromuscular junction may be increased in the presence of a normal serum esterase activity but no method of testing this possibility is available. There is certainly no evidence of an increased esterase activity to account for a disturbed balance between acetylcholine and esterase in myasthenia gravis.

#### THE HYPOTHESIS OF DEFECT IN ACETYLCHOLINE PRODUCTION

To test the hypothesis of a defect in acetylcholine production Fraser, McGeorge and Murphy (1937) tried the effect of injecting choline esters in two cases of myasthenia gravis. We found that improvement in muscle power resulted following the subcutaneous injection of 500 and 600 mg of acetylcholine 0.5 and 1 mg of carbaminoylcholine (doryl) and 25 and 50 mg of acetyl- $\beta$ -methylcholine (mecholin). Following doryl the improvement was nearly as impressive as with prostigmin, less after mecholin and but slight after acetylcholine. The effects however differed from those of prostigmin in that they appeared later, attained a maximum after some hours and did not pass off for more than twelve hours. The result following the administration of mecholin which has feeble nicotine-like properties, is especially significant and the time interval between the injection of acetylcholine and the full development of its effects is surprising in view of its rapid hydrolysis in the body. We concluded that our results suggested some defect in the production of acetylcholine in myasthenia gravis.

#### THE HYPOTHESIS OF CURARE LIKE POISONING

There is however more evidence in favour of the second hypothesis. Pritchard (1935) found that the form

of the myogram in myasthenia gravis is abnormal showing quick fatigue with high rates of stimulation and that prostigmin restores the myogram to the normal form at the same time as it produces clinical improvement. Briscoe (1936) reported that the cat's quadriceps muscle poisoned by curarine presents a myogram at fast rates of stimulation similar to that found by Pritchard in patients with myasthenia gravis and that following an injection of prostigmin the myogram is restored to the normal. At a recent meeting of the Physiological Society Walker demonstrated that if a patient with myasthenia gravis exercises a limb with the circulation obstructed by a sphygmomanometer cuff to the point of exhaustion and the pressure in the cuff is then released an increase in the weakness of the myasthenic muscles in the rest of the body occurs immediately and can be relieved by prostigmin. This suggests that some product of muscle activity either normal or abnormal has a curare like action on the myasthenic muscles. Many cases of myasthenia gravis are associated with tumours of the thymus and Adler (1937) has produced in dogs muscular weakness resembling myasthenia by transplantation of thymus tissue and by injections of thymus extracts and reports that these symptoms were completely relieved by prostigmin.

In a recent publication Minor, Dodd and Riven (1935) have reported that guanidine produced marked but temporary improvement in muscle strength in two cases of myasthenia gravis and considered the effect comparable to that of prostigmin. It was equally efficacious if given by intravenous injection or by mouth. Following intravenous injection in doses of 6 to 10 mg per kilogramme the improvement was apparent in ten to thirty minutes and was maintained for about eight hours. They quote the conclusion of Frank, Nothmann and Guttman (1923) that guanidine increases the sensitivity of striped muscle to the action of acetylcholine and consider that their observations favour the hypothesis of a decreased sensitivity of the myasthenic muscle to the action of acetylcholine.

A number of other substances besides prostigmin are known to act beneficially in myasthenia gravis notably glycine (Boothby 1934), ephedrine (Edgeworth 1930) and potassium chloride (Laurent and Walther 1935). It is probable that they are not comparable with prostigmin in therapeutic effect but a satisfactory explanation of the pathology of the disease must account for these beneficial actions and also for the well known effect of emotion in aggravating the weakness of the muscles and the fatigue.

So far we have no satisfactory explanation for all the facts. There is more in favour of a curare like poisoning of the muscles than a defect in acetylcholine production being the cause of the muscular weakness and fatigue but no suggestion that has so far been made accounts for the delayed and prolonged beneficial action of the choline esters. It is possible that the explanation of their delayed and prolonged action is quite independent of the cause of the myasthenia and that their beneficial effect is due like that of prostigmin to their ability or the ability of some resultant product, to overcome the curare like action on the muscle of some abnormal chemical substance present in myasthenia gravis.

#### IMPROVEMENT IN TREATMENT OF PATIENTS

If the principle of chemical transmission by acetylcholine has not yet solved the problem of the pathology of myasthenia gravis it has led to a great improvement in the treatment of the patients. The dose required to produce maximum beneficial effects varies with each

patient, and must be decided by trial. In an average case 2.5 mg of prostigmin by subcutaneous or intramuscular injection three times in the day at intervals of six hours will produce a striking effect and restore the ability of the patient to lead an independent and useful existence. The actual dose and the hours of administration must be adjusted to suit the individual, and oral administration in doses of about 45 mg three times in twenty-four hours can then be substituted in stages. If it is found that in the morning following the long interval of sleep without prostigmin the weakness is too great to permit the patient to get up and dress, ephedrine in doses of 1/4 to 1/2 grain by the mouth before going to sleep may be efficacious in prolonging the beneficial effect to the following morning. In many patients prostigmin in sufficient quantity to restore muscle power produces abdominal unrest and colicky pains and doses of atropine or of belladonna must be administered at suitable intervals during the day to correct the muscarine-like actions.

Harvey and Whitehill (1937a) think that the oral administration of 100 to 200 mg of prostigmin daily is the best method of treatment. Mitchell (1937) considers about 90 mg by the mouth in from three to six divided doses the most satisfactory method. Viets, Mitchell, and Schwab (1937) gave 15 mg from three to twelve times a day to twenty-three patients, and noted that belladonna or atropine is sometimes required to relieve abdominal discomfort, and that in some cases ephedrine in doses of about 3/8 grain avoids the necessity for so much prostigmin. Kennedy and Wolf (1938) treated nine patients either with subcutaneous injections of 0.5 mg repeated up to twenty-four times a day or by oral administration of 15 to 30 mg three times a day. Some patients became refractory to the influence of prostigmin.

#### QUININE IN DIAGNOSIS

Harvey and Whitehill (1937b) draw attention to the use of quinine as an adjunct to prostigmin in the diagnosis of myasthenia gravis. They point out that the objective signs of the disease may be so slight that the improvement following prostigmin may be inconclusive as a diagnostic test, and that the administration of quinine increases the symptoms to such a degree (Kennedy and Wolf, 1937) that the improvement following the injection of prostigmin can be easily recognized.

#### Effect of Prostigmin in Other Diseases of Nervous System and Muscles

Kennedy and Wolf (1937) found that prostigmin exaggerates the symptoms in myotonia, pointed out its antagonism to quinine in this disease, and drew attention to the similar exaggeration of symptoms recorded by Russell and Stedman (1936) by potassium salts. These effects are of interest in connexion with the findings of Lanari (1937), who reported that the intra-arterial injection of acetylcholine gave rise to painful muscular contractions in six cases of myotonia.

Hamill and Walker (1935) reported that prostigmin increased the motor power in cases of amyotrophic lateral sclerosis. Winkelman and Moore (1937) observed increased muscle strength in early cases of muscular dystrophy following intramuscular injections of prostigmin, and noted fibrillary tremors in one case of amyotrophic lateral sclerosis, but drew no conclusions as to its value in these conditions. Kennedy and Wolf (1938) used it in three cases of chorea, one of hemiathetosis, twelve of hemiplegia with spasticity, twelve of chronic encephalitis,

one of facial and cervical tic, two of spasmodic torticollis, one of amyotonia congenita, two of progressive muscular dystrophy, one of Westphal's pseudo-sclerosis, and one of botulism, without producing any benefit. In one patient with facio scapulo-humeral myopathy subjective and objective improvement was noted following the subcutaneous injection three times a day of 0.5 mg, but an increase of dosage produced extreme weakness.

Dr M. Kremer is at present investigating in my wards the action of prostigmin when injected by the different routes in cases with spastic condition of the muscles. He finds that after subcutaneous, intramuscular, and intravenous injections there is, as a rule, an increase in the tendon reflexes of the normal as well as of the affected muscles, and an exaggeration of the spasticity when this is due to an upper motor neurone lesion. Following intrathecal injections a different effect is obtained, as will be described later.

In a man aged 61 with generalized arteriosclerosis and left-sided hemiplegia with spasticity a dose of 2.5 mg of prostigmin by intramuscular injection, together with 1 mg of atropine sulphate to avoid parasympathetic effects, produced muscular twitching throughout most of the body so vigorous as to be painful, and in addition to the exaggeration of the tendon reflexes commonly present following this dose there

FIG 13

was an increase in the spasticity on the hemiplegic side but no increase in muscle power. He complained also of a stiffness in the neck and of difficulty in swallowing (Fig 13).

We have observed the effect of the intramuscular injection of 2.5 mg in a man of 55 who had had muscular dystrophy for seventeen years, affecting mainly the lower limbs and gluteal muscles, and who at the age of 13 had had an attack of poliomyelitis which resulted in atrophy of many of the muscles of the right arm and shoulder girdle. Twitching was especially marked in the dystrophic muscles of the legs but in addition cramp-like contractions occurred in the muscles of the left calf, in which weakness and atrophy were less than in the other muscle groups of the lower limbs. No twitching occurred in the atrophied muscles of the right arm. In this patient the twitching of the muscles was unusually severe and continued for several hours. No increase in muscle power was detected.

There is general agreement that any improvement in muscle power produced by prostigmin in conditions other than myasthenia gravis is slight and not comparable to that seen in myasthenia gravis. There is good evidence also that prostigmin by subcutaneous or intramuscular injection increases the symptoms in myotonia and increases

the spasticity in upper motor neurone lesions but has no therapeutic value in these conditions.

#### Action of Prostigmin and Choline Esters on the Central Nervous System

Plattner and Hintner (1930) showed that cholinesterase is present in the brains of rabbits, cats, and dogs. Sedman and Sedman (1937) isolated acetylcholine from cat brains. Mann, Fennelbaum, and Quistel (1935) found an inactive precursor of acetylcholine in the brains of rats, and Miller (1937) reported that physostigmine applied to the cortex of cats caused motor activity in the contralateral limbs, but there is no evidence it present that acetylcholine acts as a transmitter within the central nervous system. Observations have however been made on the effects of the choline esters and of anti-cholinesterase substances on the central nervous system in experimental animals and in man.

Schweitzer and Wright (1937a) showed that physostigmine administered to cats by intravenous injection increases the knee jerk and general reflex excitability through an action on the central nervous system, but that prostigmin and acetylcholine depress the jerk by a direct inhibitory action on the spinal cord. The same authors (Schweitzer and Wright 1937b) found that acetylcholine, doryl, prostigmin, and other anticholinesterase substances but not mechohol depress the knee jerk following intravascular injection in anaesthetized cats partly by a central and partly by a peripheral action and that while prostigmin in small doses increases the jerk by a peripheral potentiating action, larger doses have a peripheral paralyzing action.

Kremer, Pearson, and Wright (1937) observed the action of prostigmin injected intrathecally in doses of 1 to 15 mg in eight patients with spastic conditions of the muscles (one cerebral diplegic, one paraplegic due to spinal tumour, and six hemiplegics). They found that the tendon reflexes and muscle tone in the legs were decreased or abolished, and sometimes in the arms also. Such improvement in voluntary movement as was observed they considered to be due to the abolition of the spasticity. Dr Kremer is continuing these observations in my wards and comparing the effects of prostigmin when given by intrathecal injections with those following intramuscular injection. In man the effects of intravenous injection are similar to those of intramuscular injection, the tendon reflexes being exaggerated and spasticity increased, in contrast to the results of Schweitzer and Wright (1937a) in anaesthetized cats, as following the intravenous injection of relatively much larger doses they obtained depression of the reflexes from a central action. It is necessary in these observations of the effects of intrathecal injections in patients to give a preliminary injection of atropine to avoid the disturbing effects on the circulation and gastro-intestinal tract. It is not unusual for the patient to become drowsy about an hour after the injection and to remain in this state for several hours. In some instances in from two to two and a half hours after the injection symptoms of parasympathetic stimulation appear possibly consequent on the effect of the atropine wearing off, but a further injection of atropine has little or no effect on the symptoms. These symptoms may come on abruptly with vomiting, bradycardia and collapse and are presumably due to the action of the prostigmin on the vagus centre in the medulla. The train of symptoms and the abrupt onset resemble the attack reported by Goodman and Bruckner (1937) which occurred two and three quarter hours after the oral

administration of 45 mg by the mouth. Twitching of the voluntary muscles was prominent in their subject in addition to the symptoms of parasympathetic stimulation which were relieved by atropine so that a peripheral action was probably concerned and not a central one.

It is not possible at present to see the significance of these actions of prostigmin on the central nervous system and the observations on patients have not so far resulted in any therapeutic use of the drug by intrathecal injection.

#### Acetylcholine Transmission in Urticaria

Grant, Pearson, and Comeau (1936) have recorded a series of observations on six cases of urticaria in which the attacks were induced regularly by emotional disturbances, exercise or warmth. They found that the attacks could be provoked also by injections of pilocarpine and of doryl. The application by ionization of acetylcholine and more constantly of acetylcholine and physostigmine and of doryl produced local urticarial reactions in these subjects but not in normal persons. These authors considered that the effects of emotional disturbances, exercise and heating of the body were transmitted to the skin by cholinergic nerves and that the urticaria was due to an abnormal response of the skin to acetylcholine produced normally at the nerve endings. The reason for the abnormal response is obscure. If these observations are confirmed this type of urticaria must be classed along with myasthenia gravis since in both the evidence available is in favour of normal acetylcholine production and an abnormal response. For in myasthenia gravis there is an absence or diminution of the response and in these cases of urticaria an exaggerated response occurs.

#### Conclusions

The acceptance of acetylcholine as the transmitter of the effects of nervous impulses throughout a large part of the peripheral nervous system has been followed by important advances in knowledge of the physiology of the autonomic nervous system and of voluntary muscle and neuromuscular stimulation. Already, in the few years since the principle gained general acceptance a number of aspects of clinical value have emerged.

1 Many of the long established therapeutic uses of atropine and physostigmine are explained.

2 Two new substances of therapeutic value have been introduced to clinical medicine—doryl and mechohol—and their value in the treatment of intestinal distension and atony, of post-operative and post-partum retention of urine and of supraventricular paroxysmal tachycardia has been established.

3 A third new substance, prostigmin, has an established therapeutic value in the treatment of intestinal distension and atony, and has so dramatic an effect on the muscle weakness and fatigue in myasthenia gravis that it has altered the outlook for patients suffering from this disease and this therapeutic effect is of diagnostic value.

4 This action of prostigmin has led to an analysis of the cause of the muscular disability that seems likely to solve the problem of the cause of the disease.

Of greater importance I believe will be the discoveries that acetylcholine transmission will bring about in the future for all processes, tissues and organs of the body are affected by it. Further advances in pharmacology may be expected for acetylcholine lends itself readily to modifications by the synthetic chemist. Emotional disturbances have been linked with skin lesions through acetylcholine and observations have been recorded that

must lead to a better knowledge of the functions of the central nervous system. And if acetylcholine transmission should be proved to occur there as well as in the periphery, still further advances in knowledge of clinical importance may be expected.

## THE UNCONSCIOUS MIND AND MEDICAL PRACTICE\*

BY

ERNEST JONES, M D.

*President International Psycho Analytical Association*

I shall divide what I have to say here into two groups considerations bearing on the relation between the patient and the doctor, and those concerning the relation between the patient and himself, especially his disease.

Before coming to these topics themselves, however, I must first say something about the meaning of the unconscious mind in general. So immediate is the feeling of our own personality, and so intimate is our first hand acquaintance with our thoughts and emotions, that it is exceedingly hard to bring home to oneself the idea that all this self-knowledge is only very partial, that the most important part of our conscious mind is merely a selection of what has been allowed to filter through from the unconscious mind, the primary fount of all our mental processes. Now what is this unconscious mind to which so much significance is nowadays attached since Freud's epoch making discovery of it? To begin with, it represents our inborn instincts as they first manifest themselves in the dawning mind of the infant. But these never develop smoothly, as they seem to do with other animals. It is plain that in the past 50,000 years there have been brought about many extensive changes and modifications, it not in our inborn instincts themselves certainly in the adult expression of them. The difficulties we perceive in the early mental development of the individual must be related to the fact that most of these extensive changes that the race took 50,000 years to accept have to be hurriedly recapitulated in the individual in the short space of five years.

In the contact between these instincts and the outer world, and perhaps for more intrinsic reasons, difficulties and conflicts arise from the start. The apprehending of outer reality is for long preceded by a period in which the mind is ruled by fantasy, and fantasy of such a grotesque and exaggerated nature as to seem quite incredible to our conscious mind. This is one feature of the unconscious that makes it so hard to believe in the reality of its manifestations and still harder to take them seriously enough to appreciate their grim significance.

## Defensive Mechanisms

This phase of development is dominated by the problem of what in psychopathology is termed 'anxiety,' doubtless an expression of the remarkable activity on the part of the fear instinct. The majority of the mental changes that go on at this time consist of the building up of a large variety of defences against anxiety, and these defences, or 'mental mechanisms,' play an extremely important part throughout later life. Let me illustrate these at this point by a simple example—the reciprocal process of introjection and projection. When the infant's mind is terrified at feeling something bad painful and dangerous inside itself or its body, it often responds by seeking to take in something it conceives to be good and helpful from another person so as to assuage or neutralize the bad thing. I purposely say this since the primitive mind never works in abstract terms, such as 'evil impulse' etc. but always in concrete physical ones. Thus when a kind mother reassures a frightened child he does

\* An address delivered before the Swansea Division of the British Medical Association March 31 1938.

J T Ingram (*Brit J Derm Syph* February 1938) differentiates simple eczematous scosis from seborrhoeic scosis. The former is a staphylococcal dermatosis of external origin responding readily to caudal X-ray and U.V. therapy; the latter is an intractable skin manifestation of a complicated medical condition. Seborrhoeic scosis affects the beard and upper lip and is associated with the seborrhoeic diathesis, dyspepsia and septic foci particularly in nose and mouth. The treatment is that of the septic foci and of malnutrition if present with restriction of fluids and carbohydrates; the application of malachite green paint night and morning andomentations to remove the scabs. X-ray therapy may be necessary for the worst cases.

net feel that she has given him love with which to allay his terrors but an actual part of her body, milk or flesh which he feels to be good, helpful and strong. This attitude of taking in or absorbing something from another person so that it is then felt to be a part of oneself is what we mean by the word introjection. Projection is the reverse process. Here the mind deals with the bad thing by denying the possession of it and ascribing it to another person. I recently came across a pathetic example of this and am sure you have all met with somewhat similar ones. A man was dying of a very painful cancer and was being given some relief by means of large doses of morphine. In a state of drug delirium he imagined it was his nurse who had the dread disease and he uttered the most heartfelt expressions of sympathy and pity for her sufferings. Here in a critical hour the mechanism of projection succeeded perfectly in extruding from his personality all sensation of pain and distress on the condition however that his unavoidable perception of them was deflected towards the outer world.

When these defensive mechanisms function imperfectly or break down then the underlying anxiety breaks through. Else there is mental pain—that is suffering. I put at the outset these matters of anxiety and suffering with the defences against them in the foreground because I think this is the most instructive point of view from which to regard the various problems of psychopathology in general and I will add even those of the psychology of the so-called normal as well.

Some of the defensive mechanisms are when extensively employed characteristic of the psychoneuroses others of the psychoses. Neuroses and psychoses may become manifest giving rise to specific symptoms or they may show themselves more indirectly by producing what we call neurotic or psychotic character traits. In my opinion evidence of one or other of these conditions is to be found in every human being and commonly enough all of them it is simply a matter of degree. Now we know that in childhood the occurrence of manifest neurosis is universal: there is no child who escapes suffering from one or other of the familiar symptoms of night terrors, food phobias, and so on. What has only recently been appreciated is the extent to which still younger children—in the first two or three years of life—are affected by mental mechanisms especially characteristic of the psychoses. It would be inaccurate—or at all events loose language—to describe this as some authors have done as a psychotic stage of development. But one can at least say that in these phases the infant is more or less dominated by fantasies and convictions of a kind that were we to encounter them in the adult would have to be called insane delusions. Many years ago a Dutch psychoanalyst Starcke startled us by asserting that the mentality of the normal is built on a psychotic basis. Nowadays unfortunately, the sight of the world is such as to make this assertion less obviously absurd even to others than psychologists. There seems to be little doubt that there are temporal fluctuations in the extent to which these underlying mental attitudes shimmer through in social and political forms and that we are at present in a favourable position for observing them.

The grandiose achievements that men of genius have in all ages encompassed in the spheres of art of thought and of science cannot but bring inspiring and elevating reflections to any contemplative mind. The sense of wonder is vastly heightened when one admits what formidable difficulties human beings encounter in the course of their development, and what an unstable basis most of

them have to build on. It is extremely instructive to examine from this point of view the various institutions of civilization such as that of marriage of religion of class and caste and—last but not least—the numerous political theories and devices of government. Such a study reveals both how complex are the methods by which man seeks to fortify himself against his inner weakness and also how ingenious are the ways in which he has socialized those defences.

We must now withdraw from these spacious perspectives and concentrate on the more purely clinical topics before us. I alluded to them only to indicate that we are concerned here with fundamental problems of human biology of which neurotic troubles constitute only one aspect I should have said. Only a minor aspect were it not for the important fact that we owe to the neuroses through their greater perspicuity and accessibility the most fruitful approach to the deeper problems of human nature. Much of the interest of psychopathology proceeds from this consideration.

### Medical Neglect of Psychology

When psychological factors play such a large part in medical practice it is astonishing how little attention is devoted to them in medical circles and in the medical curriculum. It is of course very hard to estimate in precise figures the proportion of ill health that may be ascribed to psychological disorder. A distinguished physician recently gave as his opinion that it is as high as 80 per cent. but such an estimate certainly needs closer definition. I do not know what proportion of the populace is considered to be in completely perfect physical health. I should suppose it to be a rather small minority, but I am sure that those in perfect mental health constitute a much smaller minority. Most patients therefore who seek medical advice present a varying combination of both mental and physical troubles. Let us look at the matter in a different way for a moment. We know that the actual distress of which a patient complains often bears no close correlation to the illness which the physician thinks necessary to treat especially since his bias must for many reasons be heavily in favour of treating the physical condition rather than the mental. There is no doubt that a much higher percentage of the patient's complaints are psychological in nature than the diagnoses made by physicians would indicate. Not that this would necessarily signify their greater importance. The relative importance is something that has to be judged in each case. If a patient with a cancer presents also some neurotic manifestations we go straight for the cancer. On the other hand the fact that a severe and crippling neurosis may be accompanied by some slight bodily disturbance such as indigestion does not mean that the latter should necessarily claim precedence in therapeutic attention. The rarely attained ideal would be that judgment should be passed by someone equipped to estimate the significance of both mental and physical factors. At present the mental causes of ill-health are pitifully neglected the attention paid to them being infinitesimal in comparison with that devoted to the physical causes.

A great many reasons are given for this state of affairs most of which contain some truth—the difficulty of acquiring an adequate knowledge of medical psychology and of applying psychotherapeutic methods the apparent contradictions and obscurities in medico psychological writings, the time needed for dealing with neurotic patients and so on. It is little wonder that medicine has always hoped to evade these tasks by discovering a remediable physical

'basis for neurotic suffering, and that it clutches at every hint endocrine or other, in this direction. This seems to me to be an attitude that combines an undue optimism with an undue pessimism. It is partly based on an over-medical view of psychoneurosis being a 'disease' in the ordinary sense, the social and biological aspects not being taken into account. It is easy to see the point if one considers examples from other fields, examples that are more than analogies. Among the many problems that civilization has to deal with one may instance social conflicts, criminality, education, and the risks of distress and destruction due to the unsatisfactory uses that many ruling politicians make of their reasoning powers. Now it is no doubt arguable from a medical point of view that the difficulties I allude to are ultimately due to lesions in the brain or malfunctioning of the ductless glands. But to sit down and wait until these somatic causes are discovered, and—what is by no means the same thing—efficacious remedies found for them, would seem to be both a policy of despair and a dream of hopefulness. A teacher who adopted any such attitude about those of his pupils who were slow at learning French or coping with arithmetic would soon be dismissed from his school on the ground that he was lazily seeking excuses to evade his duty of finding psychological solutions for the difficulties in question. It may well be that in the future we shall regard the present-day attitude of the medical profession towards psychoneurotic difficulties as similarly misplaced.

No, the real reason for the medical neglect of psychology is, in my opinion, a very simple one. It is that, just as their patients physicians too are human beings. And by that I mean that, without in the least being aware of it, they shrink from the unconscious mind and have built up their life on the basis of more or less successful protections against it. The dark fantasies and fierce impulses and dread fears of the unconscious, carefully repressed from consciousness, are completely unknown, at the most some distant issue of them, such as irritability, insomnia, intolerance, etc., may be perceived. Anything that tends to draw one, however slightly nearer to the unconscious is automatically avoided, and the position of security is fortified by so called practical matter-of-fact attitudes or by any other means that may present themselves. There is no reason for supposing that members of the medical profession differ from the rest of the community in all this.

### The "Nightmare" Phenomenon

The only remark one might add is that one particular mode of defence offers itself to them with greater readiness than to other people. I mean the chance of displacing or projecting mental phenomena on to the somatic sphere. I will quote a classic example of this, which I have studied in great detail (Jones, 1931)—namely, the phenomenon called 'nightmare'. Actually this is an expression of a violent conflict between a certain unconscious sexual desire and intense fear, the admixture of these two components is infinitely varied, so that all transitions are found between the simple erotic dream, the anxious dream with seminal emission and the pure fear dream. Until a couple of centuries ago the world saw in these manifestations the action of lecherous demons who indeed often appear in the dream in various guises. It represented an important advance in thought when a scientific age sought for a more naturalistic explanation and contested the popular belief in devils, demons and witches. But if ever there was a case of emptying the baby out with the bath water it was here. Medical thought discarded not only the

fancied demons but also the sexual conflict that was the essential cause and they did this by taking full advantage of their readiest projection mechanism—somatic attribution. From now on nocturnal emissions were attributed to physical tension in the seminal vesicles, prostatic or urinary pressure, and the like, while nightmares were put down to gastric pressure on the heart, intestinal toxæmia, and a large variety of other processes implicating every system of the body. In this we safely get far away from the frightful struggle between incestuous desire and castration fear that provides the actual dynamics of the phenomena. The mediaeval writers, with their insistence on the personal sexual wishes as the causative agent, were perhaps after all nearer to the truth than modern physicians. Both used projections, on to demons or somatic processes respectively, but at least the earlier writers retained a hold on the psychological and sexual nature of the phenomenon which was lost in the later medical projection.

This historical excursus will also serve to illustrate a momentous consideration to which I wish to draw special attention. It is that in medical practice we are concerned not alone with the patient's unconscious mind, with its incalculable influence on the clinical situation, but also with that of the physician. Most of all, perhaps, we are concerned with the subtle and extensive interaction of the two. On the physician's side this produces its effect not merely in the practical handling and treatment of individual patients, but in what is possibly an even more important sphere—that of diagnosis and pathology, particularly aetiology. It will, however, be easier to expound this theme after we have considered the various attitudes the patient's unconscious displays towards disease and therefore to the person treating that disease. I will next take these two topics in order: the influence of the patient's unconscious on his relation to himself (including any disease present) and on his relation to the physician.

### Influence of the Patient's Unconscious

The first of these two topics naturally divides itself into the problem of neurosis itself and the attitude of the patient's unconscious to physical disease. To understand the latter one must have some knowledge of the former. There are fortunately many descriptions of the psychopathology of neurosis now available (Deutsch, 1932; Freud, 1929; Jones, 1938; Mitchell 1921; Stephen, 1933), and I shall confine myself here to emphasizing certain fundamental features of the condition. First of all, neurotic manifestations do not themselves constitute a disorder except in a purely clinical and descriptive sense, actually they are only the visible symptoms or signs of an underlying disorder, just as jaundice is a sign of hepatic disturbance. They result from an excessive inner tension which has been provoked by some intolerable thwarting or privation. The tension itself proceeds from an unresolved conflict which has often been stirred to fresh activity by some current situation. They express in a variously disguised way both sides of this conflict and thus are always what may be termed *compromise formations*. In the conflict the important elements are sexuality, aggression, fear, and love but these are involved in such an extraordinarily complicated fashion that one cannot describe the two sides of the conflict in any simple terms.

These four or five sentences state in an exceedingly condensed form the most essential basis of our knowledge about the meaning of psychoneuroses but it is a basis that has been reached only as the result of extremely detailed studies of the characteristic unconscious

mechanisms that determine the structure of such formations, and the state of affairs is actually much more complex than I have just indicated. Let us look at it in another way. Thwarted and repressed impulses provide the active dynamic urge that starts everything going. These meet with opposition from other instinctive attitudes and the conflict generates first fear then mental pain and misery. This is the disorder itself, but then there comes into play a whole series of defences, one or two of which I mentioned earlier, and the manifest neurosis is the result. It is really the resultant combination of all the factors containing elements from each one of them. It expresses therefore something of the primary repressed impulse, something of the resulting anxiety and distress, and something of the defensive attitudes. The proportion of these varies considerably in different cases. In one the gratification of the repressed wishes is prominent so that the neurosis brings unmistakably positive advantages to the patient who is correspondingly loath to renounce it. In another the anxiety breaks through and dominates the clinical situation either directly or in the form of protective phobias. In yet another case the defensive mechanisms play the largest part and then the clinical type is apt to assume the form of what we call a character neurosis.

#### Factors in Neurosis Formation

It is important to distinguish between the current and the essential factors in neurosis formation just as it is to distinguish between the exciting and essential causes of tuberculosis or heart disease. In the aetiology of neurosis we commonly though by no means always find current factors such as overwork, over excitement, privation, grief, misfortune. Yet none of these can by itself produce a neurosis. It evokes one only if certain specific conditions are present in the unconscious—namely a serious unresolved conflict dating from childhood, one with which the current factors can become associated. The process set up is what we call regression. The emotional responses reanimate the older ones and revert to an older type. This is the reason why a real cure of any neurosis necessitates the exposure of the essential childhood basis and the resolving of conflicts then left in an unsatisfactory state.

The central content of the repressed impulses may be summed up in two words: incest and murder. When we reflect that these refer to loved parents, that bitter hostility has to fight against the strongest feelings of dependence and affection it is not astonishing that no easy solution can be found. On the physical side also there are many bewildering ideas with which the young child has to grapple: the problems of cleanliness, clashing with the extraordinary significance that excretory processes have for the infant, the instinctive knowledge of coitus with the unknown dangers accompanying the idea of penetration, the sex differences with their implication of castration. Small wonder that no child escapes an infantile neurosis, tantrums, fears, eating difficulties, destructive and other manifestations which every adult does his best to discount.

If a neurosis proceeds successfully to its logical extreme it ends in a state of inhibition more or less extensive according to the severity of the conflict. It seems plain that the function of a neurosis is on the one hand to retain in an unaltered infantile form certain repressed impulses, and on the other to keep at bay the anxiety and distress that these impulses are prone to bring in their train. It is often very remarkable what extensive inhibitions people will bear before they consider them as

symptoms and seek for therapeutic help. Permanent sexual frigidity or a sexual perversion that confines gratification to the narrowest possibilities, the crippling effects of a phobia that may forbid all social life or even going out of doors (as with an agoraphobia), these and many similar restrictions are cheerfully borne if only the impulses and dread they cover are thereby successfully kept out of sight and never enter consciousness.

#### The Patient's Attitude towards Treatment

These considerations about the nature of neuroses enable us to understand a prominent and peculiar feature in the patient's attitude towards therapeutic help. It is of course common enough with physical disorders for there to be a conflict between patient and doctor over the question of what is to be treated. The patient naturally wishes to be relieved of whatever symptoms are giving him distress, while the doctor is more concerned with abolishing the cause of the symptoms than with merely alleviating them. No doubt the actual treatment will vary with the strictness of the doctor's professional code of ethics, since it is undoubtedly easier to fall in with the patient's wishes and alleviate the symptoms than to insist on giving him the trouble of having the underlying causes investigated and dealt with. Still there is no doubt about what the medical attitude ought to be in such a situation, even if in practice doctors sometimes depart from it. Now with the neuroses the conflict between doctor and patient is much sharper. It must be very rare in organic disease for no wish for cure to exist in the patient's mind, but with neuroses this state of affairs is the rule. One may say that they constitute the only condition where the patient comes for help to sustain the disease and resists every effort to cure it.

To give up a neurosis would signify to the neurotic mind which has not been able to encompass any alternative to surrender certain cherished wishes and also since this is inherently unthinkable to dispense with the only protection it knows against the accompanying anxiety and mental misery. When a person is disturbed by neurotic symptoms his distress is only in part due to the painful effect of the symptoms themselves. What disturbs him far more is the inner feeling that his defensive systems are beginning to break down, which is indeed what the presence of manifest symptoms means. What brings him for help is his need to strengthen and reinforce these defences—that is the neurosis itself.

This curious situation is further complicated by an even more peculiar feature—one which leads to a unique problem in therapeutics. With organic disease one can reckon not only on the patient for some will towards cure, but still more so on the part of the doctor, unless he panders to the patient's preference for the alleviation of symptoms, his whole attitude is in favour of curing the condition. Now with the neuroses it is different. Here also there is agreement between doctor and patient, but unfortunately this time in the opposite direction—namely, of avoiding a cure. In a certain very important sense doctor and patient are psychologically in a similar position. Both have had to fight against their unconscious tears and to build up various complicated defences against them in the course of their early development. Both therefore show the strongest disinclination to open up these defences and expose the repressed material behind them. It is far easier to turn the other way to discount or deny the significance of any signs of underlying emotions, to get away as far as possible from them to strengthen and encourage what is called the will power. This is of course what the patient in particular wants, since it is

the only way he knows of to combat the neurotic affliction. And, with one single exception, this also has been the aim, avowed or otherwise, of all the various methods of psychotherapy from the beginning of medical history.

### Psycho-analysis

The exception is, of course, psycho-analysis. And by psycho-analysis I mean *real* psycho-analysis, not the strange things that nowadays often pass by that name. The aim of psycho-analysis is in exactly the opposite direction to that of other forms of psychotherapy. It is to uncover and resolve the conflicts that underlie the whole neurosis. In this way it strengthens the ego, including the "will-power," not by the method of direct encouragement which has such palpable limitations but by diminishing the unconscious anxieties that are the real cause of its weakness.

This procedure, however, cannot be carried out except by someone who is prepared to face calmly the contents of his own unconscious mind, and who has had the personal experience of resolving the conflicts and anxieties in it. Without this his endeavours to help his patients would constantly be thwarted, unknown to him, by the powerful inner forces making for the opposite solution to the analytic one. At first sight no doubt it seems strange to ask that a doctor should have to undergo the same treatment as that which he proposes to employ with his patients. In no other branch of medicine is such a thing thought of. When it happens, as for instance with pulmonary tuberculosis, then certain advantages are perceived—the doctor is perhaps better able to appreciate the difficulties of the regime—but no one would dream of suggesting that the staff of a sanatorium must necessarily be tuberculous. With psycho-analysis, however, the whole situation is radically different. The very tool the analyst employs in the treatment is his own unconscious mind, and if this is not clear, perspicuous, and able to function quite smoothly he would be in the position of a histologist using a rusty and muddy microscope—everything would be distorted by artefacts.

### Relation between the Unconscious Mind and Organic Disease

I should like now to say something about the relation between the unconscious mind and organic disease. Bodily processes are of the greatest interest to the mind, and especially so to its primitive infantile, and unconscious layers. They are therefore one of the commonest ways by which unconscious mental attitudes find expression. We are very familiar with some forms of this—for instance, in conversion hysteria, where an unbearable loathing may express itself as chronic vomiting, or a wish to expel imaginary poison may lead to chronic colitis. But it is certain that the effects of unconscious attitudes go far beyond this, and it is at present impossible to set limits to our knowledge concerning the extent to which they may influence bodily processes. It is, for instance, probable that the greater part of ordinary dyspepsia takes its origin in this way. Much work in this direction has recently been done on very varied conditions ranging from asthma and thyroid syndromes to duodenal ulcer.

Where on the other hand the organic disorder is essentially of physical origin we still have the question of how the mind reacts towards it since this may not only influence the patient's attitude to treatment but may also exacerbate the physical condition itself or complicate it by the addition of neurotic symptoms. The unconscious invariably interprets every physical illness as a personal

attack, which it colours with a projection of its own aggressivity. In other words, someone has either malevolently or sadistically assaulted the person. This, it is felt, is equivalent to introducing a bad poisonous material that will corrode all that is good within, will exhaust and drain vital material, and prevent the acquiring of beneficial sustenance. The unconscious then conceives of help in coping with the invasion in one of two ways: the doctor is either to offer something good that will neutralize the malevolent foreign body or to display a violence greater than this. We are familiar with these two broad types of treatment, psychologically regarded, and perhaps also with corresponding types of doctor. The one is illustrated by a soothing cough medicine or a gentle manipulative massage, the other by most medicines or by surgical operations. I say "most medicines," for it is a familiar experience that a medicine with a pleasant taste is apt to be suspected of impotency.

There are three features in organic disease that are prone to activate a latent neurosis. In the first place every form of injury or illness signifies privation or deprivation in one form or another, whether it be interference with sleep, with freedom of movement, of eating, of working, or of other activities. Now, as I remarked earlier, privation is the characteristic starting-point for all neuroses. It sets in action the typical mechanisms of regression back to infantile fantasies and wish-fulfilments with all the symbolism and disguises that clothe neurotic processes. With the details of these we are not here concerned.

In the second place the unconscious invariably responds to any kind of physical illness or injury by generating anxiety. Some of this is of course conscious, but much more is unconscious. We know that one of the two main functions of every neurosis is to provide a barrier or support against unconscious anxiety, so that is a second way in which organic disorders stimulate any latent neurosis.

Finally, most physical illness causes either pain or some other kind of suffering, and thus provides material for the various tendencies in the unconscious that seek for suffering. This search for suffering is perhaps the most remarkable trait in human nature, being so paradoxically anti-biological, but it is hardly possible to exaggerate its importance psychologically, and even the most experienced of us are constantly being surprised by its power and range. It has several sources. There is the curious component of the sexual instinct called masochism, which is far more subtle and widespread than is commonly thought. Then there is the tendency to self-punishment which plays a large part not only in neuroses but in everyday psychology. It comes from the fact that an important part of the conscience is itself unconscious, and that part is far more primitive and ruthless than the conscious part with which we are familiar, though of course even the latter can at times inflict considerable suffering and pain by remorse. Most subtle and dangerous of all, however, is the tendency of the mind, from fear and other motives, to turn its repressed aggressive impulses against itself instead of against the outer world. Suicide is of course its extreme form, but it has a thousand other manifestations. It is a motive that has always to be watched for, since in both neurosis and organic disorder it may succeed in baffling the most skilled therapeutic efforts.

### The Unconscious Mind of the Doctor

I have not time to develop the interesting theme of the ways in which irregular functioning of the unconscious mind of the doctor may interfere with his clinical

judgment in making diagnoses and deciding on treatment but I am persuaded that the potential skill of most doctors is considerably reduced by such aberrant activity. The commonest example is probably the way in which doctors share popular superstitions about the danger of cold air but the grimmest example of all is of course when the patient's death results from such mistakes but short of this I think one could trace more errors in medical practice to unconscious interference with knowledge than to lack of knowledge itself.

### Conclusion

In summing up I would repeat the two main contentions of my paper: that there are few cases in which the unconscious mind of the patient does not play a part in the clinical situation and further that the fact of the doctor possessing an unconscious mind is one the importance of which is commonly overlooked.

## UTERINE RUPTURE FOLLOWING CAESAREAN SECTION

BY

C. E. B. RICKARDS, M.B., M.C.O.G.

Chief Assistant to the Gynaecological Unit, Manchester  
 Royal Infirmary

According to Eardley Holland (1920) 4 per cent of Caesarean scars give way during a subsequent pregnancy or labour. Often this type of rupture is not accompanied by any abnormal signs or symptoms and the surgeon on opening the abdomen to perform a second section is amazed to find a bulging sac of liquor amnii protruding through the old scar. At other times the clinical picture is one of shock or haemorrhage. None of these cases however resemble the ordinary type of uterine rupture which so often occurs as a terminal event in cases of obstructed labour and is described in the obstetrical textbooks.

Many cases of rupture of the uterus following a previous Caesarean section have been reported and the condition may give rise to a perplexing and bewildering variety of signs and symptoms. An attempt is here made to classify this type of uterine rupture into five groups, with the object of facilitating its diagnosis.

### Group I

In this group the rupture occurs through an old upper segment incision and the placenta is situated away from the uterine scar. This is a common type.

Mrs. A., a woman who came under my care at St. Mary's Hospital, Manchester, belonged to this group. This patient was admitted to hospital during the last month of her first pregnancy. Her diagonal conjugate was estimated to be 9 inches and her interspinous and intercrural measurements were 9 and 9½ inches respectively. As the head showed no signs of entering the pelvis a medicinal induction was attempted. She did not tolerate the quinine however so drugs were discontinued and the patient was allowed to start labour spontaneously. Trial of labour was unsuccessful and I delivered her by Caesarean section twenty-three hours

after the onset of the pains. The classical operation was performed and the uterus sutured with two layers of interrupted catgut, an additional continuous suture being used for the peritoneum. She had a febrile puerperium the temperature reaching 101° on several occasions between the second and the fourteenth day after operation. She was discharged from hospital on the twenty-second day in a satisfactory condition.

In 1936 she became pregnant again. During this second pregnancy the head never showed any sign of entering the pelvis; it was extremely mobile and rode high above the inlet. It was often palpable in one or other iliac fossa. Towards the end of the pregnancy "overlap" could be demonstrated if the head were pushed over the pelvic inlet and pressure applied to the fundus of the uterus. As the patient had had a very fair trial of labour with her previous child and as this second infant showed no signs of engaging in the pelvic cavity it was decided to perform another Caesarean section.

We arranged to admit her into hospital on July 20 but on the morning of this same day she came in as an emergency. On being questioned she told us that she had been in labour fourteen hours before reporting at the hospital. The pains she said had been very bad most of the time but their severity had diminished and they had been less regular during the last one and a half hours. Her general condition was very good. The pulse was 80 and the blood pressure 120/80. She was having pains but they were rather irregular and niggling in character. Immediate Caesarean section was considered advisable.

On opening the abdomen I was very much surprised to find that the scar of my previous operation had given way along two inches of its length. An intact bag of membranes was bulging through the aperture. The rest of the scar which was a fibrous one was thinned out and appeared to be on the point of bursting. The placenta was situated on the posterior wall of the uterus and was nowhere near the scar.

This case impressed me very much by its lack of signs and symptoms. Many similar cases are to be found in the literature. Occasionally the bulging sac of liquor has been palpated through the abdominal wall (Casagrande 1933). Sometimes foetal limbs have been recognized protruding through into the sac. These splits are often only discovered at operation. Prognosis is good when proper treatment can be administered.

### CHARACTERISTICS OF GROUP I

- 1 Rupture tends to take place during labour.
- 2 Little or no haemorrhage occurs and therefore the pulse remains good.
- 3 The pains may become niggling in type after the scar has started to give way.
- 4 The bulging bag of membranes may sometimes be palpated through the abdominal wall.
- 5 Prognosis is good provided that suitable treatment is available.

### Group II

Group II consists of cases in which the rupture occurs through an upper segment incision and the placenta is situated underneath the old scar. This type of case is more serious and presents a different clinical picture. When the placenta is situated underneath the old scar a gradual erosion of fibrous tissue by the placental villi occurs (Hornung 1929). This erosion is an insidious one and may cause marked attenuation of the scar during the latter part of pregnancy. In this type of case therefore rupture is said to be more liable to occur before the onset of labour. The eating away of the scar may be associated with vague pains in the lower abdomen (Potter 1930). As the process is gradual haemorrhage is seldom severe.

until the onset of labour, when the uterine wall is pulled away from the placenta and the sinuses are left gaping

A good example of this type is mentioned by Holland (1920). In his case the first Caesarean section was performed in 1914 for contracted pelvis. In August 1915 the patient was readmitted to hospital. She was pale, and the pulse was 120 and of poor volume. A diagnosis of concealed accidental haemorrhage was made. On opening the abdomen it was found that the old scar had ruptured along one and a half inches of its length. Placental tissue protruded through the rupture and there were about two pints of blood in the abdominal cavity.

Another typical case has been reported by Casagrande (1933). In this instance the patient had her first Caesarean section at the age of 37. The puerperium was febrile. The second pregnancy terminated in a breech delivery with no complications. With the third pregnancy five days before the expected date of delivery she presented a picture of considerable shock with marked pallor, pale lips and a weak and rapid pulse. On opening the abdomen the placenta was found bulging through the centre of the scar. There was a considerable amount of blood in the abdominal cavity.

#### CHARACTERISTICS OF GROUP II

1 Gradual rupture tends to occur towards the end of pregnancy. This may be accompanied by vague pain in the lower abdomen. Such pain should therefore never be ignored.

2 After the onset of labour haemorrhage occurs, and may be of considerable severity.

3 Prognosis will not be so favourable as in Group I, and will depend very largely on the amount of intra abdominal haemorrhage.

#### Group III

In Group III the rupture occurs after a previous lower segment section. Several cases belonging to this group have been reported during recent years. The incidence of subsequent rupture is said to be reduced by using the lower segment technique. I myself feel doubtful about this, as I have seen very attenuated scars in the lower segment.

Mayer (1934) has reported a case of this sort in which operation revealed a very considerable haemorrhage suggestive of a laceration involving one of the uterine arteries. Perez and Tallaferró (1937) also reported a case, but in this instance part of the placenta was attached to the outer wall of the uterus adjacent to the scar, showing that the scar must have given way early in pregnancy. Trillat (1934) considers that these ruptures usually take place during labour and there is an absence of pain. Jager (1931) has recorded a case in which rupture extended into the bladder, causing marked haematuria.

#### CHARACTERISTICS OF GROUP III

1 Rupture is said to take place during labour. There is no very convincing evidence on this point.

2 Haemorrhage may occur, due to the extension of the laceration laterally into the uterine arteries.

3 Rarely the bladder may be involved, giving rise to haematuria.

#### Group IV

Group IV comprises cases in which the rupture is complete through an upper segment incision, and the child, within its bag of membranes, is expelled into the abdominal cavity, the placenta remaining *in situ*. In this type of case the uterine scar gives way along its entire length, the contractions persist and the child is extruded into the abdominal cavity. The foetal heart sounds almost invariably

disappear and foetal movements cease. The physical signs are characteristic. The uterus is felt to be pushed over to one side, and the child, floating in the abdominal cavity, is very easily palpable.

An interesting example of this variety has been described by Tottenham (1931).

This patient developed pneumonia after her first Caesarean section. Labour with the second pregnancy started at midnight. At 8.45 a.m. she was admitted to hospital. She came by tram and walked a distance of a quarter of a mile up a steep incline. On admission the pulse was 80, she was in a very good condition, and the real state of affairs was discovered only on abdominal palpation. Section revealed a foetus lying enclosed in its bag of membranes in the peritoneal cavity. The placenta, in the vicinity of the scar but apparently not underlying it, was in the uterus. There was hardly any bleeding.

#### CHARACTERISTICS OF GROUP IV

- 1 Foetal heart sounds cease as a rule.
- 2 Foetal movements usually stop.
- 3 The uterus is pushed over to one side.
- 4 The foetus, lying free in the abdominal cavity, is easily palpable.

#### Group V

In this group the rupture is complete, through an upper segment incision, and the child, with its placenta, is extruded *in toto* into the abdominal cavity. A case described by Holland (1920) belongs to this group.

This patient had had a Caesarean section performed in March 1914 after she had been in labour over eighteen hours. Convalescence was febrile. In March 1916, when she was readmitted to hospital, spontaneous rupture of the uterus occurred. There was collapse, anaemia, with cessation of pains, and the foetus was very easily palpable. The dead child, the placenta, and much blood were in the peritoneal cavity. The patient made a good recovery.

Potter (1930) stresses that the most dangerous cases from the prognostic point of view belong to this group, and says that this type is usually associated with severe haemorrhage and collapse, and often results in the death of both mother and child. Such cases fortunately are rare.

#### CHARACTERISTICS OF GROUP V

- 1 Often associated with severe intra-abdominal haemorrhage.
- 2 Foetal heart sounds are absent.
- 3 Foetal movements are absent.
- 4 The uterus is pushed over to one side.
- 5 The foetus, lying free in the abdominal cavity, is easily palpable.

#### Conclusion

All patients who have been subjected to Caesarean section should have subsequent confinements under skilled supervision and within access of a fully equipped operating theatre. If the indication for a second Caesarean is absolute, then the operation should be performed either during the last week of pregnancy or at the onset of labour. Unnecessary delay in these cases can do no good, and may be the cause of rupture of the scar with its attendant dangers. Should the first Caesarean have been performed for any condition other than gross pelvic contraction, such as placenta praevia, minor degrees of contraction, etc., and should it be considered advisable to allow a trial of labour with a subsequent child, then the patient must be under the closest supervision not only

during labour but also during the latter part of pregnancy. Any abnormal symptom, particularly that of lower abdominal pain, must be regarded with suspicion.

### Summary

Rupture of the uterus during a subsequent pregnancy or labour is not uncommon in those who have undergone Caesarean section. This type of rupture has been divided into five groups and the characteristics of each group briefly indicated.

My thanks are due to Dr F. Lacey for permission to quote the case of Mrs. A. under Group I.

## THE NERVOUS COMPLICATIONS OF MEASLES

BY

A C E COLE, M.B., M.R.C.P.

(From the Department of Medicine, University of Cambridge)

Nervous complications are recognized to follow most of the exanthemata and the incidence is probably highest after measles. Boenheim (1925) gives the incidence in Berlin as 0.4 per cent, and this may not be considered an over-estimate if we remember that as well as the severe cases which impress so much as to be included in the literature, we must also include the minor cases of mere drowsiness or slight meningeal irritation.

### Pathology

This has been studied by Wohlwill (1928), Ferraro and Schaffer (1931) and Greenfield (1929). The last named has summarized the abnormalities to be found in the central nervous system under three headings: (1) congestion and haemorrhage; (2) perivascular infiltration; (3) perivascular demyelination. The pathological findings appear to be identical with those occurring in post-vaccinal encephalitis and in the forms of encephalitis following certain other acute fevers (as for example mumps and chicken pox); it has therefore been suggested, especially by Greenfield, that the post-vaccinal and other forms of encephalitis which follow eruptive fevers are not directly due to the virus of the preceding fever but to another independent virus which is either stimulated to activity or is directed against the nervous system by the exanthem. The phenomenon of demyelination also occurs in disseminated sclerosis and Schilder's disease, and it is possible that there is some connection between them. The changes in the cerebrospinal fluid are variable. There is usually a moderate increase in the cells, mainly lymphocytes, up to about 200 per cmm. The protein may also be increased.

### Clinical Manifestations

These have been summarized by Ford (1928) who collected most of the authentic cases in the literature and added twelve of his own. He distinguishes six groups—

1. Mild and Transient Diffuse Cerebral Symptoms—These include stupor, headache, vomiting and possibly

even convulsions. There may be a suggestion of meningism but the symptoms point to involvement of the brain rather than the meninges and to a general toxic effect rather than local inflammatory damage. These cases may recover completely or may pass into one of the further groups.

2. Multiple Focal or Diffuse Lesions of the Nervous System—The accompanying physical signs include spastic weakness of the extremities, tremor, choreic or athetoid movements, aphasia or ataxia, or the condition may simulate either tuberculous meningitis or epidemic encephalitis.

3. A group of single focal cerebral lesions, aphasia or hemiplegia being the commonest symptoms.

4. Cerebellar Syndromes of Varying Degrees of Severity—There may be localized or generalized ataxia, intention tremor, loss of muscle tone, slow or scanning speech and nystagmus.

5. Paraplegia and Spinal Cord Syndromes—An acute ascending paralysis may occur.

6. Other nervous complications—for example toxic psychoses and papilloedema.

The whole series of Ford's cases yield a mortality of about 10 per cent, which compares favourably with the mortality of 55 per cent in post-vaccinal encephalitis in the English epidemic of 1922-3. About 60 per cent of the survivors showed residual symptoms, such as weakness, ataxia, mental defect or personality change. The time of occurrence of the nervous symptoms was extremely variable; they might appear as early as the height of the fever or even in the prodromal period or as late as a month afterwards. The commonest times were on the third, fourth or fifth day of the exanthem and between the tenth and twentieth days of convalescence. As might be expected, the incidence was mainly in childhood, following the much higher incidence of measles at this period.

### Case Report

The following case is an example of the post-febrile variety of measles encephalitis.

The patient was a married woman aged 31 with two children aged 6 and 3. The elder child was taken ill on August 26, 1936, and when seen by his doctor on the 29th presented a typical mild attack of measles from which he made a good recovery. The younger child became ill on September 3. His rash did not appear till the 14th, six days later. He also made a good recovery.

On September 21 the mother complained of headache, malaise and aching pains in the limbs; there was some coryza. The doctor saw her on the 23rd; her temperature was then 101° F. there was no rash and no Koplik's spots were seen. In spite of this measles was still suspected as she had not previously had an attack. Her main complaint was of cough, but no physical signs were found in the chest. She had definite photophobia, preferring the blinds down. On September 27 two or three Koplik's spots were found and the diagnosis seemed certain. No rash, however, developed; a temperature of between 100° and 103° F. persisted together with the cough, which was associated with no physical signs until October 3, when there were moist sounds at the left base.

On October 5 she was admitted to Addenbrooke's Hospital, Cambridge, under the care of Dr C. H. Whittle. She was then mentally depressed and looked ill, with slight cyanosis and an increased respiration rate. The only physical signs were in the lungs posteriorly, low down between the scapulae, where there was impairment of note with bronchial breathing and fine rales. Her condition improved and by October 8 there were no physical signs; her temperature was normal and a radiograph of her lungs showed no lesion.

At about this time she became euphoric and her depression departed, it was also noticed that her speech was becoming slurred. On October 11 slurring was more pronounced, and she volunteered the statement that she saw double on looking to the left. On examination her pupils reacted to light and accommodation but the left pupil reaction was not sustained. There was no ptosis and no abnormalities of the cranial nerves were detected except for weakness of both sixth nerves, especially the left. There was no weakness or altered sensation of the limbs but all tendon reflexes were exaggerated, the plantar responses were equivocal. The fundi showed some blurring of the disk margins—about the same on both sides.

**October 14**—Lumbar puncture was performed. The fluid was not under increased pressure; it was contaminated by blood and so useless for further tests.

**October 16**—The patient started vomiting, and did so several times daily for the next three days, the vomiting being unaccompanied by nausea.

**October 19**—Speech was still slurred and there was marked euphoria. Slight facial weakness was observed on the left side only. The disks were still slightly blurred. There was intention tremor of both hands more on the right, and dysidiadokokinesis of the right hand, with past-pointing to the right. The tendon reflexes were exaggerated, abdominal reflexes were absent on the left and weak on the right.

**October 26**—The weakness of face and alteration of reflexes were much less marked. There was nystagmus coarse and horizontal on looking to the left, finer and vertical on looking to the right. There had been very marked mental weakness with delusions and hallucinations, during the preceding days, but this had slightly improved.

**October 30**—Her speech had now become more articulate and lower in pitch and her appearance was more that of a normal woman. Practically all physical signs had disappeared, except intention tremor on the right and some nystagmus on looking to that side.

**November 17**—She was at this date discharged quite well, having been able to walk and to look after herself for over a week.

#### AFTER HISTORY

**November 26 1937**—A little more than a year after her discharge the patient attended the follow-up department. She had been very well and fit in every way, both mentally and physically, and neither she nor her family had noticed any sequelae. On examination reflexes, tone, power, and sensation were all normal; is were the fundi. There was slight intention tremor more marked on the right hand. Dysidiadokokinesis was present on the right and there was slight horizontal nystagmus on looking to that side. The position sense was normal.

#### Discussion

There would seem to be no doubt at all that this was a case of encephalitis beginning with multiple focal and diffuse lesions, and later concentrating on the cerebellar functions. Fortunately, the sequelae were minimal, affecting cerebellar function only and unaccompanied by mental defect or personality change.

The possible differential diagnosis of acute disseminated sclerosis would seem to be excluded on two counts: first, by the mental symptoms in the acute attack, and, secondly, by the absence of any further development in over a year.

Whether the illness followed an atypical attack of measles without the rash can be less certainly claimed. The existence of these *formes frustes* of measles is well recognized. Box (1937) states: "Some of the mildest attacks are aberrant, the rash failing to appear, and only Koplik's spots giving a clue to the disease." Blackfan (1933) says: "the fever and catarrhal symptoms may follow the usual course with an eruption which is

scanty or atypical. Koplik's spots are found even in the atypical cases." The same period of thirteen days existed between the illness of the first and the second child as between the second child and the mother, while the second child took longer than usual to develop the rash. In both their cases the measles was mild in type. The clinical development of the illness was such that there can be little doubt that it was measles. Koplik's spots were seen, and the chest symptoms and early photophobia were characteristic. Only the rash was lacking.

My thanks are due to Dr C. H. Whittle for permission to publish the case.

## SULPHANILAMIDE THERAPY IN MENINGOCOCCAL MENINGITIS

### REPORT ON THREE CASES

BY

**T. C. MORTON, O.B.E., M.D., M.R.C.P., D.P.H.**

*Wing Commander R.A.F.*

**V. S. EWING, M.B., Ch.B., D.P.H.**

*Wing Commander R.A.F.*

AND

**J. D. EBSWORTH, M.R.C.S., L.R.C.P.**

*Civilian Medical Practitioner, Princess Mary's R.A.F.  
Hospital, Halton, Bucks.*

The following cases are considered worth reporting in view of the widespread interest in the treatment of meningococcal meningitis by drugs of the sulphanilamide group. Two of these cases were due to a Type I meningococcus, the second is included because, although bacteriological evidence was lacking, the case both clinically and epidemiologically was almost certainly of a similar type. The site of the disease in meningitis is accessible by spinal puncture, and the inflammatory exudate can be seen, estimated, and readily examined by cytological and bacteriological methods in a way that is rarely available in other acute infections.

#### Treatment

1. Prontosil soluble was given intravenously (20 ccm of a 2.5 per cent solution), and this dose was repeated at eight-hour intervals for from two to three days. In addition 1½ grammes of prontosil album were given in the twenty-four hours by mouth. The first two or three intravenous injections were followed almost immediately by vomiting which was not repeated with subsequent injections, apart from this no ill effects were noticed.

2. All prontosil was stopped forty-eight hours after the cerebrospinal fluid became sterile and the cell count had dropped to a fairly low level. Contrary to L. J. Willien's experience this was not followed by a relapse, he continues the drug by the mouth for ten days after the symptoms and laboratory findings have returned to normal.

3. In addition anti-meningococcal serum was given intrathecally twice a day for three days. This is

probably not necessary as I. J. Willien has treated a series of six cases with sulphanilamide alone with excellent results. We feel however that until further experience has been gained in the treatment of this disease with sulphanilamide compounds it is not justifiable to withhold serum. Animal experiments also tend to show, according to Brown that in mice infected with meningococci the administration of both agents simultaneously produced a greater degree of protection than either of the agents by itself.

## Case I

A recruit aged 17 of excellent physique (weight 132 lb) was admitted at night on February 13 1938 in a comatose condition. It was afterwards ascertained that he had felt sick and had vomited the day before. He had remained on duty until lunch time on the 16th when he lay down on his bed and later on was found unconscious. On admission marked neck rigidity and Kernig's sign were present. The diagnosis was confirmed by lumbar puncture, meningococci were seen in the direct smear and a profuse growth of Type I meningococcus was

obtained on culture. His temperature fell to normal in twenty-four hours and he made an uninterrupted recovery, apart from the usual serum rash.

### Case II

A well built youth, aged 15, weight 119 lb, was admitted on the night of March 22 1938. His temperature was 100.6° on admission. He was completely deaf, but was able to answer written questions and appeared very anxious. There was marked neck rigidity and a positive Kernig sign was present. Auriscopic examination was completely negative, both tympani being intact and normal. An examination of his central nervous system, apart from the involvement of both eighth nerves and a definite papilloedema of the optic disks, was negative. Interrogation later revealed that he had reported sick with a headache on the day of admission and had been treated for nasopharyngitis, and towards evening he suddenly became stone deaf in both ears. He states that there was no tinnitus or vertigo, but as he was in bed the latter might not have been noticed. A turbid cerebrospinal fluid was obtained on lumbar puncture containing 10,200 cells per cmm (95 per cent polymorphonuclears). No organisms were seen in direct smears and all cultures were sterile. The diagnosis of cerebrospinal meningitis with eighth nerve involvement was made on clinical grounds, and treatment was started. He made a complete recovery from his meningitis, but the deafness, which is of a nerve type, persists, although it has improved slightly. On March 30 examination showed a complete nerve deafness of the left side, on the right side a shouted voice could be heard at three feet.

### Case III

A youth aged 16, of average build (weight 124 lb), was admitted at noon on March 23, 1938. His temperature was 103.4°. He complained of intense frontal headache, photophobia, and neck rigidity, an erythematous rash was present on the trunk and upper limbs, with a few scattered petechiae. The diagnosis was confirmed by lumbar puncture, scanty Gram negative diplococci were present in the direct smear, and after forty-eight hours incubation a Type I meningococcus was grown. Apart from a herpes labialis and a serum rash which appeared on the 28th he has made an uninterrupted recovery.

### Comment

Three cases of meningococcal meningitis have been treated with prontosil and anti-meningococcal serum. We were greatly impressed with the rapidity in resolution of the pathological findings in the cerebrospinal fluid, together with the dramatic clinical improvement in the patients' condition, and on comparing these cases with others treated in the past with anti-meningococcal serum alone we feel that the results obtained were largely due to prontosil.

The object of pushing prontosil soluble during the first seventy-two hours is to sterilize the cerebrospinal fluid before morbid changes with their lasting sequelae have time to occur.

In the second case the eighth nerves were already involved when treatment commenced, and an unfavourable prognosis as regards hearing was inevitable.

In view of the American experience it is probably wise to give sodium bicarbonate grain for grain with sulphaniilamide to combat acidosis.

In our opinion the giving of sulphaniilamide intrathecally is unnecessary.

The use of prontosil album orally to combat the carrier problem opens a large field for experiment.

Our thanks are due to Group Captain E. W. Craig, M.C. Officer Commanding Princess Mary's R.A.F. Hospital for his kindness, help and co-operation.

## Clinical Memoranda

### Chronic Schizophrenia with Remission following a Spontaneous Epileptiform Seizure

Contrary to the experience of most workers, this case affords yet another example of a cardiazol remission occurring in an advanced case of schizophrenia of some eight years' standing.

The patient, Mrs. X, aged 34, was admitted to Warlingham Park Hospital on April 9, 1931, suffering from schizophrenia of the depressed type of some six months' duration. Prior to admission she had swallowed methylated spirits and said she hoped she would die. When admitted she was notably self-absorbed and evinced little interest in her surroundings, being also indifferent about her dress and personal appearance. Shortly after admission she was described as dull and resistive, having auditory hallucinations and requiring to be fed by tube. Her subsequent history was one of apparent progressive dementia, with faulty habits, complete self-neglect, and impulsive suicidal tendencies extending over years. She became mute, and from time to time exhibited catatonic stuporous tendencies, alternating with periodic excitement. Her physical condition, never robust, deteriorated, as will be seen from the following note dated March 11, 1938.

'She remains physically in poor condition, being emaciated and still losing weight, despite full extra diet. Her weight is now 5 st 2 lb, indicating a loss of 10 lb in the last two months and this without evidence of organic disease, mentally she is restless, excitable, and impulsive continually discarding her clothing, and is both wet and dirty. She will crouch naked in a trivistic attitude, silent, morose, and withdrawn, portraying little evidence of mind.'

On April 12 1938, at 2 p.m., she had a spontaneous epileptiform seizure, a phenomenon unprecedented in her case. The seizure lasted some three minutes and, beyond transient confusion, produced no other mental change that day. During the next two days, however, she showed great mental improvement, becoming relatively accessible, talking rationally though hesitantly, and sitting up in bed knitting. This sudden change in an apparently 'lost' and demented patient was striking enough to call for considerable comment. The improvement was not maintained and within the next few days the patient gradually lapsed into her former state.

On May 3 cardiazol treatment was begun despite her poor physical condition, in the hope of regaining remission by therapeutic convulsions. A dose of 4 ccm of a 10 per cent solution of pentamethylenetetrazol was given intravenously, and produced a typical major epileptic fit. The procedure was repeated on May 9 and the patient showed almost immediate mental improvement, the same evening becoming partially accessible and conversing rationally though with considerable retardation. Since then the treatment has been repeated every third day, the dose at no time having exceeded 5 ccm of the 10 per cent solution. The patient has continued to show marked mental and physical improvement, being indeed scarcely recognizable as the same person. She spontaneously asks to be allowed to assist in the ward, converses brightly and rationally, and writes sensible letters to her relations. She shows every promise of making a good recovery, and her physical improvement is almost equally marked. All faultiness of habit has disappeared, and she now takes pride in her personal appearance. So far she has had nine therapeutic seizures and treatment is still being continued.

An interesting side aspect of this case lies in the fact that her husband, regarding her as hopeless, contemplated divorce proceedings under the new Matrimonial Causes Act. Within the short period of one month the complexion of this case has totally altered, and it affords an instance of the need for extreme caution before finally

adjudging an apparently hopeless case is incurable. The case, moreover, exemplifies Muller's observation (1930) that where epilepsy intervenes in the course of schizophrenia the schizophrenic symptoms tend to remit. This observation following similar observations pointing to a constitutional antagonism between idiopathic epilepsy and schizophrenia made previously by Nyiro and Jablonszky (1929) on the treatment of epilepsy is the rationale of the convulsion therapy which is producing similar brilliant results in certain other forms of mental disorder.

I have to thank Dr. T. P. Rees, medical superintendent for permission to publish this case.

WM H. SHIELLY, M.B. D.P.M.  
Senior Assistant Medical Officer, Warrington  
Park Hospital, Surrey

## Influenzal Meningitis Treated with Soluseptasine and Lumbar Puncture Recovery

In view of the recent literature on this apparently rare condition (*British Medical Journal* 1937 2 797 and *Lancet* 1937 2 1410) another case of influenzal meningitis in an adult with recovery may be described.

## CASE REPORT

The patient, a man 60 years of age and 19½ st. in weight was first seen on October 19 1937 after a few days illness the outstanding features of which were pains in the back and legs, headache, dizziness and intense drowsiness. For a fortnight before taking to bed he was aware of a great desire to sleep on every possible occasion. Apart from this symptom he felt in his usual health.

When examined he was drowsy and so giddy that he could not sit up in bed. He complained of pain in the back and legs and of headache. His temperature was 102° and his systolic blood pressure 210 mm Hg. There was no sugar or albumin in the urine and no other abnormal physical sign. Next day his condition was definitely worse. He was so drowsy that he could scarcely be roused and by evening he was comatose. There was now slight nuchal rigidity, the pupils were fixed in mid-dilatation and Kernig's sign was present. The knee and ankle jerks were normal in reaction. Abdominal and cremasteric reflexes were absent. There was no apparent further involvement of cranial nerves. Lumbar puncture revealed a slightly turbid fluid under pressure. The fluid was examined by Dr. Kyle of the Western Infirmary of Glasgow with the following result: "Cell count 138 per cmm, chiefly polymorphonuclear leucocytes. On examination of films from the centrifugalized deposit polymorphonuclear leucocytes were numerous. Small Gram-negative bacilli resembling *B. influenzae* were the only organisms seen. On culture no growth was obtained on appropriate media."

Lumbar puncture was repeated daily for the next four days with immediate improvement in the patient's mental condition following each puncture. The fourth and last lumbar puncture showed that the cerebrospinal fluid was still very slightly translucent but not under pressure.

Soluseptasine (May and Baker's preparation of the sulphonamide series) 3 grammes as a dose was given eight hourly for seven days and after four days the temperature became normal. The patient's only complaint was slight occipital headache and general weakness. His systolic blood pressure was now 146 mm Hg. A rapid and continuous improvement set in leaving no signs of any involvement of the central nervous system and the patient was able to leave his bed for a short time on the twenty-third day of his illness. His final convalescence was quite uneventful.

Milngavie, Dumbartonshire

## Aspirin Poisoning

A fatal case of aspirin poisoning is sufficiently rare to warrant its recording although there was in this instance no very unusual feature.

## CLINICAL HISTORY

A woman aged 30 was admitted as a voluntary patient into St. Andrew's Hospital in September last with a diagnosis of dementia praecox. Periods of depression were noted but no suicidal tendencies had been exhibited. Frequent medicinal doses of aspirin had been indulged in before her admission.

By some means unknown the patient obtained a bottle of 100 five-grain tablets of aspirin and after defacing the label had swallowed some if not all of them between four and five o'clock on Saturday. At 7 p.m. she became restless and two hours later when this had increased vomited undigested food. At 11 p.m. she said she had taken some aspirin and thought that it was that that was causing the sickness. This and other statements to the same effect were not believed because the possibility of her having obtained the aspirin was not entertained and she often suffered from delusions. Restlessness, insomnia and mild delirium continued throughout the night. Sweating and hyperpnoea became obvious later and at 7 a.m. she had the first of three epileptiform convulsions. Coma then supervened and she died on Sunday at 9.30 a.m. about seventeen hours after taking the poison.

## FINDINGS AT NECROPSY

A post mortem examination was carried out the next day and the following is a summary of the findings.

The body was that of a very thin dehydrated female. Cyanosis was not marked. The blood was dark in colour and fluid. The brain was congested. The lungs were congested and contained little air. In the dilated and discoloured stomach were 12 oz. of brown fluid containing numerous gritty particles. The stomach wall was inflamed and necrotic. The distended bladder contained 16 oz. of clear yellow urine. Sections of the kidney, liver and stomach were made. The kidney showed marked congestion with red cells in the tubules and shrunken glomerular tufts. The efferent veins and sinuses of the liver were engorged. Necrosis and submucous oedema were found in the stomach wall. Very strong reactions with ferric chloride were obtained from the stomach contents and urine and rough estimations suggested a dose of at least 400 grains.

## COMMENTARY

Dyke in 1935 reported fully a case of poisoning by about 430 grains which recovered after energetic treatment. Neale in 1936 reviewed five cases of poisoning four of which were fatal. The general opinion appears to be that recovery after 400 grains may be expected.

This case presented most of the classical signs, the latent period, the restlessness, sweating, dehydration, hyperpnoea and the terminal convulsions.

As treatment is by no means ineffective, early diagnosis becomes important. The ferric chloride reaction is a delicate test for salicylic acid and should a strong reaction be obtained in the urine with a weak or absent Rothera's test and a positive reaction with the chloride of iron in the cerebrospinal fluid the diagnosis of aspirin poisoning is more than a probability.

I am indebted to Mr. Bernard Prett, H.M. Coroner and Dr. Brooks Keith for permission to publish this case.

## Reviews

### THE THYROID SURGICAL PATHOLOGY

*Surgical Pathology of the Thyroid Gland* By Arthur E. Hertzler M.D. (Pp 298 238 figures 21s net) Philadelphia and London J B Lippincott Company 1937

Professor Hertzler's book on thyroid disease had had three editions, the last being reviewed in these columns about two years ago. In this review comments were made of the unorthodoxy of many of the author's statements. Professor Hertzler has now brought out a larger volume dealing with the surgical pathology of the thyroid gland, in which he elaborates his own views, which often run counter to accepted opinion. The book is therefore stimulating to read, refreshing in its racy way of expressing matters, but dangerous unless read critically. In his preface the author suggests that he is only following accepted opinion to its ultimate conclusion when he urges that, if removing a part of a diseased gland is beneficial to the patient, nothing could be more logical than to assume that removing the whole will be better.

In brief synopsis the thyroid case is shown to present a serial story, in early life the thyroid gland attempts to adjust itself to function harmoniously with the other endocrine glands, or, partaking too much or too little of something, it becomes the colloid goitre of adolescence. There being no anatomical change, spontaneous recovery is possible. If the enlargement does not regress with the passage of time the goitre changes its shape, developing non-toxic bosselations. During this period neither patient nor doctor can quite decide whether the goitre is toxic or not, and in their combined optimism they regard it as non-toxic. Then follows the period when everybody learns that the goitre is toxic and the heart already a thyrotoxic one. Professor Hertzler describes these stages as the non-toxic diffuse goitre, the non-toxic nodular goitre, and the toxic nodular goitre, of which there may be atypical varieties. There is also the toxic diffuse goitre, with exophthalmos and increased metabolic rate (Graves's disease).

This clinical classification does not give a true differentiation, however, in all cases there is a mixture of hyperplasia and recession, and, as Professor Hertzler admits the absence of thyrotoxic manifestations does not attest that the heart is not being injured by the goitre. He believes that the cardiotoxic element arises from degenerative changes in the goitre, some changes of the colloid are postulated the nature of which is not known. This is because no definite cellular pathology is found in the cardiotoxic goitre. The essential thing is to detect impending toxicity before there is heart damage, to study the genesis of toxicity rather than the bosselations or nodules. The basal metabolic rate is a measure of the cellular hyperplasia and gives no measure of the toxicity or degeneration and no warning of the progress towards a damaged heart. Non-toxic nodular goitres do not represent a stage of innocence but the threshold of more important changes which will surely come in advancing years. Logically the surgeons should not be frightened to aid the cardiologists with total removal of the whole gland. The author has never seen post-operative myxoedema, and doubts if it exists. The surgeons then, should push matters to a complete try-out though he admits that the clinical judgment of surgeons is not infallible.

Pathologists and physiologists are content for the most part to worship at the shrines of the past. Now, accord-

ing to Professor Hertzler, myxoedema may be due to a deleterious product of a diseased gland, and in myxoedema the surgeon may be culpable in not removing enough gland. These hypotheses will need more substantiation than mere statement. The illustrations are numerous, typical, and beautifully reproduced.

### VITAMINS DURING PREGNANCY AND LACTATION

*Der Vitaminhaushalt in der Schwangerschaft mit besonderer Berücksichtigung der Vitamine A und C* By Dr. Med. Gerhard Gaethgens. Volume 24 of *Medizinische Praxis* (Pp 161 21 figures RM 12, bound RM 13 20) Dresden and Leipzig Theodor Steinkopff 1937

This book gives a short summary of the metabolic processes concerned with proteins, fats, and carbohydrates. The chemistry and chemical method of estimation of vitamin C (*l*-ascorbic acid) are described, together with the application of this method to the "saturation" test for human beings. The function of vitamin C in the animal body is discussed (a part in the oxidation-reduction processes). Carotene and vitamin A are treated similarly, but unfortunately the only measure of vitamin A used by this author is the "Lovibond unit" (Incidentally, Coward is erroneously credited with having used the occurrence of xerophthalmia as a criterion of vitamin A deficiency).

The main part of the book deals with the findings of the author and of other writers on the vitamin C, carotene, and vitamin A content of the blood and urine during pregnancy and lactation, an estimate of the pregnant woman's daily need for vitamin C, the storing of these factors in the placenta and foetal tissues, and their presence in very variable amounts in the amniotic fluid. There is a long account of the importance of vitamins C and A in lactation as evidenced by the daily determinations of the volume and vitamin C content of the milk and urine of many women. The need of the lactating mother for vitamin C is shown to be greater than for the woman at ordinary times. The finding for vitamin A was similar. The antagonism of the thyroid gland and vitamins A and C is discussed at some length, with the "greed" of certain organs for storing certain vitamins. The last section is devoted to the practical aspect of feeding the pregnant and lactating mother. There is a list of vitamin concentrates available in the market and a short table of the vitamin contents of the commoner foodstuffs. References are given for most of the results of other workers quoted in the text.

The book is well printed and the illustrations well drawn and reproduced.

### ALCOHOLISM

*Alcohol One Man's Mead* By Edward A. Strecker M.D. Sc.D. and Francis T. Chambers, Jr. (Pp 230 10s 6d net) New York The Macmillan Company 1938

The reader in search of general information on the subject of alcohol will be disappointed. From the sub-title one is not surprised to encounter an early reference to 'allergy' but the term is employed in this connexion in a rather peculiar application. There is, states the author, nothing more humiliating or disgraceful about having a psychic allergy to alcohol than there is about having a physical allergy or sensitivity to fish or strawberries.

A rather startling confession printed in the introduction is made the basis of a special claim to authority. The author expresses his indebtedness to his collaborator whom he proclaims to be one of the few men who have

intelligently studied the problem of alcoholism who has established his key position for the understanding of the problem since he himself was in alcoholic whose investigation and cure of his own case has insured the capacity to comprehend all the factors involved in the production of alcoholism. Yet it cannot be said that despite this promise the result is very illuminating. The greater part of the book is occupied with wearisome reiteration with psychological details in description of lurid cases with explanations of the urge towards alcoholic indulgence which are on the whole elementary and yet are put forward as if profound discoveries. The last chapter of thirteen pages on psychological and nutritional factors is fairly comprehensive but much too abbreviated and concentrated for the uninformed reader though it might serve as a convenient list of references for the more experienced. It devotes itself for the greater part to an insistence on the relation of hypoglycaemia to alcoholism and wastes space in describing at length the investigation in the laboratory of four cases when one would have sufficed.

The final sentence. We feel that the most satisfactory treatment of alcoholism consists of an intensive psychological—re-educational approach reinforced by a sensible correction of physical damage and particular attention to a carefully considered nutritional program epitomizes the problem succinctly. The attempt thus to deal with it has not been avoided but the method employed cannot be appraised.

## MATERIA MEDICA, PHARMACOLOGY, AND THERAPEUTICS

*Materia Medica Pharmacology, Therapeutics and Prescription Writing for Students and Practitioners.* By Walter Arthur Bastedo PhM MD ScD FACP. Fourth edition reset. (Pp 778 81 figures 30s net.) Philadelphia and London W B Saunders Company 1938.

*Textbook of Materia Medica Pharmacology and Therapeutics.* By A S Blumgarten MD FACP. Seventh edition completely revised. (Pp 845 illustrated 12s 6d net.) New York The Macmillan Company 1937.

The textbook by Dr W A Bastedo of Columbia University is well known and well established. The first edition appeared in 1913 and now a fourth reaches us for review. It is interesting to note that though it is only five years since the last edition yet the author mentions eighteen important drugs which now make their first appearance and states that numerous important articles have been rewritten. He writes from the standpoint of a practising physician but fully recognizes the need for laboratory research in providing a sound basis for rational therapeutics. He remarks: "I believe that as the outcome of critical laboratory research and the adoption of laboratory methods in clinical research we are at the dawn of a new era of simple and practical therapeutics an era in which knowledge will supplant credulity on the one hand and scepticism on the other and in which fewer drugs will be used but better treatment given." In general the volume gives a very clear account of pharmacology and therapeutics and great care has been taken to deal adequately with recent developments. The author states that he has included many drugs only to condemn them and it is questionable whether such substances do not occupy too large an amount of valuable space. The best attitude to take to such remedies is however a difficult problem and Dr Bastedo has found space for full and clear discussion of the action of all drugs of known value.

The textbook by Dr A S Blumgarten of New York is intended primarily to assist nurses in their class work and practice. It was first published in 1914 and now

has reached its seventh edition hence it evidently fulfils its purpose in a satisfactory manner. The author has had the difficult task of explaining the pharmacological actions of drugs to students with a limited knowledge of physiology. He has made a free use of diagrams and the colour diagrams deserve special notice on account of the effective manner in which they illustrate certain fundamental facts about drug action. The book covers a very wide field and naturally treats the subject in as simple a manner as possible but great care obviously has been spent on its revision and adequate accounts are given of recent advances in such subjects as the action of benzadrine the use of insulin in treatment of schizophrenia protamine zinc insulin sex hormones and vitamins. In general the volume gives a very clear account of the essential facts of pharmacology.

## BOYD'S PATHOLOGY

*A Textbook of Pathology. An Introduction to Medicine.* By William Boyd MD LL D FRCP FRSC. Third edition thoroughly revised. (Pp 1064 459 figures 16 coloured plates 4s net.) London Henry Kimpton 1938.

Professor William Boyd's *Textbook of Pathology* a third edition of which has now appeared has attained remarkable popularity. The author's flair for vivid expression makes it more readable than most works of the kind and his constant endeavour to relate morbid changes to the clinical features of disease has rendered an important service to the better study of pathology. The motto of this work might be a sentence in its original preface.

A world of disordered function lies revealed in any lesion it we only have the eye to see it. This edition has been modified by including a large number of brief references to subjects or aspects of subjects previously untouched space for which has been made by placing certain sections in small type and by introducing many new illustrations some in colour. In so comprehensive a work and especially in one which discusses aetiology with such freedom it is easy to find statements which are disputable and sometimes perhaps even misleading but the general effect on the student's mind of the author's enlightened method of treating his subject can only be admirable.

## BLOOD GROUP HEREDITY

*A Critical Investigation of the Blood Groups and their Medico Legal Application.* By Dawood Matta MB ChB PhD. Faculty of Medicine Publication No 11. (Pp 231 80 tables No price given.) Cairo Egyptian University 1937.

The established theories of blood group determination and heredity are benefited by an occasional overhaul. Dr Matta's thesis contains the results of a considerable body of research into the existing theories of blood group inheritance. In his preface he acknowledges help from Professor John Glaister of Glasgow University with whom he has been associated in this work for some years. He covers much well trodden ground but reaches some interesting conclusions. Besides confirming the serological bases of the four main groups he finds that proof has been obtained of the existence of subgroups A and A<sub>1</sub>, B and B<sub>1</sub> and their combinations with each other. The difference between these subgroups is he says quantitative. He confirms Schiff's observation on the existence of an agglutinin O not only positive in character but equal in value with the characters A and B in the foundation of the system of the four groups. This observation is interesting in that before Schiff's work the character O was always regarded merely as an indication of the

absence of both A and B, and as a recessive and not a dominant character. Dr. Matta uses its quantitative variation in the cells of the various subgroups to formulate a new classification containing thirteen subgroups. He also claims to have shown it in the cells of certain AB persons. He cannot explain these results by applying any of the hitherto accepted theories of heredity, and has therefore formulated the hypothesis that the three agglutinogens O, A, and B are all Mendelian dominants and that the genotype of each individual is composed of four genes representing one, two, or three agglutinogens, two of which are transmitted by each parent to the child. He confirms the work which has shown the existence of the three types M, N, and MN, and regards the existence of a weak N as probable. He says that the application of blood grouping to cases of disputed paternity should be restricted to exclusions based on the simple Mendelian law that a child cannot possess an A or B character unless at least one parent possesses it. He does not consider that the subgroups can be applied to this purpose until their inheritance has been corroborated by work on a larger number of families than the ninety-nine which he has investigated. He also considers that the inheritance of the characters M and N should not be used judiciously until certain points of relationship between them, and also certain questions concerning the inheritance of N<sub>2</sub>, have been cleared up. This opinion, if confirmed, would postpone the application to affiliation proceedings of much work that has already been widely accepted, and which has, in fact, been applied every day for some years in the courts of various European countries.

### Notes on Books

*Physiological Chemistry of the Bile* by HARRY SOBOTKA (Baillière, Tindall and Cox, 13s. 6d.), will be welcomed by all those who stand in need of a comprehensive digest of the vast literature relating to biliary function. For a thorough and well-documented survey nothing better could be desired, and, when taken in conjunction with the same author's companion volume on the chemistry of the steroids, it constitutes, but for the omission of the bile pigments, a complete exposition of the chemistry and physiology of the bile and its constituents. While the author gives good reason for leaving out the pigments, many are likely to hold the view that such essential components might with advantage have been included, even though their treatment had to be disposed of in brief summary and in the absence of a detailed chemistry of the pyrrol derivatives.

Professor CAMILLE LIAN presents the French Medical Annual for the seventeenth time, and this review of principally French work on medicine during the past year ranges from 'abscess of the lung' to Wassermann reaction-ified. The practical aspects of the subjects discussed are well stressed. The publisher of *L'Année Médicale Pratique* is René Lepoint, Paris, and the price 35 fr.

*Die Pathogenese des Ertrinkens in Zusammenhang mit der Behandlung* by Dr. C. J. MÜHLIEFF is published in Berlin by Carl Heymann, price R.M. 8. In it the author describes a series of experiments made on animals. Drowning and resuscitation were performed and sections were subsequently taken of the lungs. Dr. Mühlief concludes that the first step in resuscitation should be to empty the air passages of water and that it is important not to start artificial respiration until this has been done. He finds that when the bronchi are plugged with water

artificial respiration can cause extensive injury to the alveoli of the lungs. He emphasizes the fact that undue violence in artificial respiration can very easily produce such injury.

Bentley and Driver's *Tables of Qualitative Chemical Analysis* (H. Milford, 1s.) provides the directions for a beginner in the practical study of the subject in a handy and useful form. The directions are suitably condensed and abbreviated so that the student may memorize the facts easily as he works and thus lay a good foundation for the further development of his study. What is lost by this condensation is better left for subsequent study after the student has gained experience in the practice of the scheme of treatment here given. The scheme is that which is quite usually followed in schools.

## Preparations and Appliances

### NON-SLIP RUBBER CRUTCH PADS

Dr. Sydney H. Keys (Ruislip) writes:

I have recently had brought to my notice, by Mr. E. W. Coleman of South Ruislip, samples of non-slip shock-absorbing crutch pads. Ordinary pads of plain rubber will slip on highly polished floors and water being a lubricant to rubber, will cause rubber to slip on wet surfaces. With Mr. Coleman's latest patents these defects are overcome in the non-slip crutch pad and also in the non-slip ferrule for invalid sticks.

The diagrams show a rubber crutch pad formed with a socket (b) for fitting on to the crutch. The surface of the pad is composed of a number of concentric projections separated by air spaces, the projections including a central soft rubber stud (c), an inner hard rubber ring (d), an intermediate soft rubber ring (e) and an outer hard rubber ring (f), the air spaces between the projections are also indicated (g).

The soft rubber projections (c and e) are more prominent than the hard rubber projections (d and f). When the pad is pressed upon the ground the soft rubber projections (c and e) make the first contact and are compressed so that they spread into the air spaces. The width of the spaces (g) is such as to permit the spreading to take place without any overlapping of the hard rubber projections by the soft rubber. The effect is that when the pad is pressed hard upon the ground the surfaces of the soft rubber projections (c and e) are pressed back to the same level as the top of the hard rubber projections (d and f), the latter being resistant and taking the wear whilst the soft rubber projections exercise an elastic grip on the ground and prevent slipping.

# Nova et Vetera

## THE BMA AND MEDICAL REFORM

In Mr E. Muirhead Little's centenary *History of the British Medical Association* there is a chapter on the Association and Medical Reform a matter which was kept in the forefront of policy from 1837 onwards. So closely has this subject been interwoven with the life of the Association that it is difficult to treat of it apart from other medical affairs. The first important step was taken in 1839 when the Association presented to Parliament a memorial on the urgent need for reform of medical education and of the status of the practitioner and praying for the necessary legislation. Contact was made at the House of Commons with the MPs Warburton Hawse and Thomas Wakley Editor of the *Lancet* who were bringing forward Bills for the regulation of medical education and the restriction of unqualified practice. The Bill introduced by Mr Hawse MP for Lambeth came up for second reading in March 1841 but was counted out. In 1845 the Secretary of the Association received instructions to send a copy of the report of its Medical Reform Committee at once to Sir James Graham in reference to a Bill he was introducing but nothing came of this renewed effort. Five years passed and then Sir George Grey brought forward another abortive Medical Bill.

### A Letter from the Founder

In 1852 Mr George Hastings MP son of the Founder and Secretary of the Medical Reform Committee drifted on behalf of the Association a Medical Bill which however shared the fate of all its forerunners. We have received from Dr D. A. H. Moses M.C. a copy of a letter now in his possession written by Sir Charles Hastings evidently referring to that Bill. The letter is as follows:

Worcester  
March 5 1853

My dear Mr Nunneley

From the letter you will have received from my son you will perceive that the Committee were determined to take their stand on the Bill and to go boldly to Lord Palmerston who willingly receives us.

Nothing must keep you away and you must secure as many Members of Parliament as you can to accompany the Deputation to Lord Palmerston.

If you have any means of securing Sir James Graham do so by all means and get him to support the Bill.

We shall meet at my son's Chambers 4 Paper Buildings Temple at ten o'clock in the morning of the 17th to arrange the preliminaries.

Believe me

My dear Mr Nunneley

Yours very truly

CHARLES HASTINGS

Thomas Nunneley Esq.

Two years later at the Annual Meeting of the Association held in York the Medical Reform Committee recommended the reintroduction of this Bill and steps were taken to organize support of the measure in Parliament. It had a first reading in the House of Commons but went no further. At the Annual Meeting of 1857 in Nottingham Sir Charles Hastings announced that the Right Hon. W. F. Cowper MP, was proposing to introduce a Medical Reform Bill in the next session of Parliament. This was the measure which became law on August 2 of the following year as the Medical Act 1858. Under it the General Medical Council was constituted and Sir Charles Hastings became one of the four Crown nominees upon that Council retaining his seat from November 13 1858, to November 13 1863.

Thomas Nunneley F.R.C.S. to whom our Founder's letter is addressed was mainly known to the profession as a provincial ophthalmologist and to the public as a medical witness in the trials for murder of William Palmer and William Dove but he was also for six years surgeon to the General Infirmary at Leeds and had a name for judgment and skill in operating. From its formation in 1832 Nunneley was a most active member of the British Medical Association and in 1869 the year before his death he read the Annual Address in Surgery at the Leeds meeting.

## NIELS STENSEN, 1638-86

As a medical student of 23 Niels Stensen dissecting in the house of Gerardus Blasius (Blas) at Amsterdam, discovered and graphically described the duct of the parotid gland in the head of a sheep, and despite jealous efforts on the part of his teacher to take the credit for himself has survived in the anatomical eponym Stensen's duct ever since. Had he accomplished no more fame would not have passed him by. Studying the structure of muscle with the aid of the microscope he anticipated much of our modern knowledge. His motor fibre has become our fasciculus his most minute fibril is our elementary fibre and his proper membrane we now call connective tissue framework. His conception of the nature of muscular contraction was far in advance of his time. He found the duct of the sublingual gland and elucidated the mechanism of the secretion of tears by the lacrimal glands. A neat and clever dissector he was mathematically inclined sober and practical. In his discourse on the *Anatomy of the Brain* in 1669 he sternly rebukes both Willis and Descartes for their fanciful theories.

Extremely versatile even for a versatile age Stensen is sometimes described as the father of geology. He was a pioneer too in the scientific study of crystals investigating their growth by accretion and the phenomena of light refraction. In 1666 he was invited by Ferdinand II to become his court physician at Florence. But in the following year occurred a tide in his affairs which completely changed his outlook and revolutionized his career. Converted from the Lutheran to the Catholic faith and later receiving the titular honour of Bishop of Titiopolis in Greece he lived a life of severe self-denial gradually undermining his health. Though for a time he taught anatomy in his native town of Copenhagen the power of conviction and the eagerness for knowledge had deserted him. He died in 1686 at the age of 48 and was buried in Florence. The tercentenary of this restless noble sincere and entirely unselfish character who possessed a true genius for friendship was commemorated by the Section of Historical and Cultural Medicine at the New York Academy of Medicine on March 9 1938, with a comprehensive and authoritative paper by Dr Anne Tjomsland. Stensen is often known by his Latin name Nicolaus Stenonis inaccurately Steno.

W. R. B.

John Freke the 250th anniversary of whose birth occurs this year was the first curator of the museum and the first ophthalmic surgeon at St Bartholomew's Hospital and in 1736 described myositis ossificans progressiva. A friend of Henry Fielding he is mentioned twice in *Tom Jones*. He died in 1776. A chandelier carved by him in oak and heavily gilded hangs in the Steward's office at St Bartholomew's.

Under the title of *Some Forgotten Medical Memorials* an anonymous writer in the April issue of the *Journal of the Royal Naval Medical Service* gives short historical notes concerning Sir John Richardson Sir Alexander Armstrong, Robert McCormick Frank Toms W. T. Donville M. C. Bain David Walker George Bass and Elliott whose names have been given to various sites.

## ACETYLCHOLINE

Professor F R Fraser's Croonian Lectures, the last of which appears in our columns this week, give a lucid and well-documented account of the present state of knowledge of the therapeutic uses of acetylcholine and related substances, and afford an opportunity for discussing briefly a few points in connexion with one of the most interesting chapters in modern physiology. Experimental work has shown that acetylcholine is liberated in nerve endings in many parts of the body, including the terminals of all the parasympathetic and somatic motor nerves and the preganglionic fibres of the whole autonomic system. There are excellent reasons for believing that acetylcholine is probably concerned with the transmission of the nerve impulse in this region, but it would be unwise to conclude as yet that it is the sole mechanism involved and that no other agencies play a part. Be that as it may, those properties which make acetylcholine highly suitable as a nerve transmitter make it highly unreliable as a therapeutic agent. The transmitter must be a very unstable substance which can be disposed of with great rapidity, so that the peripheral response of the organ to the nerve impulse should not be unduly prolonged. As Professor Fraser has pointed out, when acetylcholine is administered to man by any route it is rapidly destroyed by the specific enzyme cholinesterase in the blood and in the tissues, so that its effects, even when given in comparatively large doses, are uncertain and evanescent and usually disappear completely in a few seconds or minutes. It is improbable, therefore, that much can be expected from the use of acetylcholine in the treatment of high blood pressure or of intestinal atony. To overcome the difficulties enumerated one may use other and more stable choline esters which act for longer periods or else employ drugs of the eserine or prostigmin type which inhibit the action of cholinesterase, preserve naturally formed acetylcholine, and so to speak make it available for therapeutic purposes.

Professor Fraser discusses the use of carbaminoylcholine (doryl) and of acetyl- $\beta$ -methylcholine (micholyl). Both substances have been tested in visospastic conditions but although symptoms

were relieved no permanent effects have been noted on the blood pressure in cases of hypertension. It is claimed that attacks of paroxysmal tachycardia may be brought to an end by injections of these drugs, but anyone with experience of the natural history of this condition would hesitate to dogmatize about the relation of the treatment to the result. Apart from possible uses in ophthalmology it seems well established that doryl especially is useful in overcoming post operative intestinal atony and retention of urine due to weakness of the bladder wall. Of the anticholinesterases studied prostigmin has proved to be the most useful, both for its stimulating action on the bowel and, more especially, for its dramatic ameliorative effects in myasthenia gravis. Eserine, although it has the same general actions, is less satisfactory for systemic purposes as it produces in man severe cardiovascular depression, vomiting, headache, and general malaise. Although the muscular weakness of myasthenia gravis can now be readily controlled no final conclusion has yet been reached as to the underlying disturbance. There is at present no proof of either insufficient formation or excessively rapid destruction of acetylcholine at the nerve endings in muscle. On the other hand, recent observations by Dr Mary Walker indicate that in this disease a substance may be formed at the motor endings which resembles curare in blocking the transmission of the impulse from nerve to skeletal muscles. When a myasthenic patient exercised the arms (after the blood supply to them had been blocked) to the point of exhaustion Walker found that on release of the circulation weakness developed in the muscles of the rest of the body, suggesting that some chemical agent had been freed from the ischaemic limbs. Further observations on these points will be awaited with much interest.

There is still no direct evidence that acetylcholine is concerned with the transmission of impulses in the central nervous system. The researches of Schweitzer and Wright,<sup>1</sup> however, show that both acetylcholine itself and anticholinesterase drugs act directly on the spinal cord in cats, and it has now been confirmed<sup>2</sup> that prostigmin given intrathecally produces striking changes in reflex activity in man. A recent paper by Schweitzer and Wright<sup>3</sup> throws further light on this complex problem. They examined the pharmacological actions of two derivatives of the dimethylcarbamic ester of hordenine—namely, the hydrochloride and methiodide. Both substances are anticholinesterases, they are equally potent *in vitro* and have identical actions on muscle and other peripheral organs, yet they

<sup>1</sup> *J. Physiol.* 1937 89 165 384 90 310  
Kremer M, Pearson H, E S, and Wright, Sam on H, ed  
1937 89 21 P  
<sup>2</sup> *Ibid.* 1938 92 422

differ fundamentally in their central effects the hydrochloride being convulsant and the methiodide a central depressant. Further experiments<sup>1</sup> suggest that these differences are to be attributed mainly to the physical (rather than chemical) properties of the substances concerned. The hydrochloride gives rise in the body to a derivative containing tertiary nitrogen, which is lipid soluble and so can probably penetrate into the interior of the nerve cells. The methiodide on the other hand gives rise to a water soluble derivative containing quaternary nitrogen, which is perhaps compelled to remain outside the surface membranes of the nerve cells. More extensive investigations suggest that this general rule probably applies to the anticholin esterase group as a whole so far as their action on the central nervous system is concerned. These conclusions will have to be taken into serious consideration when any theory of central transmission is ultimately promulgated.

## TREATMENT OF PNEUMONIA

We referred not long ago in these columns<sup>2</sup> to the great advances which have been made in the United States in the study of pneumonia and in the direction of making serum treatment for this disease generally available. One of the great organizations taking part in this campaign published two years ago a useful practical handbook entitled *Lobar Pneumonia and Serum Therapy* which we reviewed at that time.<sup>3</sup> A second edition has now appeared with a significant change in title—*Pneumonia and Serum Therapy*—the word 'lobar' being omitted. Implied in this change is one of the advances which have taken place in these two years and are recorded in this edition. The study of the 'higher types' of pneumococcus has shown that some of these types, which more often occur in bronchopneumonia than the classical Types I, II and III are capable of causing a severe form of the disease such of these infections by the higher types as have been subjected to serum treatment have been found amenable to it. Among the data assembled in this volume are the results including some hitherto unpublished elsewhere so far obtained in treating pneumonia due to Types V, VII, VIII and XIV. Another new factor in the situation is the advent of rabbit therapeutic serum. It will be remembered that in this animal according to recent observations antibodies to the pneumococcus are produced more rapidly and in greater quantity than in the

horse and they have the advantage owing to the smaller size of the rabbit globulin molecule of greater diffusibility in the body. Although results with this serum continue to be encouraging they are not considered to have reached such a stage as to justify general use. Besides reporting these new developments and bringing up to date the imposing mass of evidence on the results obtainable with serum treatment this volume remains an invaluable practical guide in which every detail of procedure connected with serum administration, including preliminary typing and tests for hypersensitiveness, is carefully and simply explained and illustrated by diagrams. Special emphasis is laid on the importance of blood culture as a prognostic aid and a guide to serum dosage. It is also emphasized that even in apparently mild cases there may be a rapid or gradual transition from a condition of apparent safety to one of great gravity<sup>4</sup>, for this reason every case amenable to serum treatment should receive it. This is a vital question and it is here that the American attitude differs from that usually taken here whether this difference is justified by a lower mortality from pneumonia and a generally more favourable course followed by the disease in this country is a matter which as we have pointed out before calls for careful investigation and decision.

The stupendous effort which has organized the treatment of pneumonia in some of the eastern States of America and achieved such results as have been mentioned has been financed by the States themselves by insurance companies, and by large charitable funds. It has no parallel in this country and as we pointed out in reviewing this subject before, serum treatment cannot be made universally available without concerted action, in which it seems that public health authorities should take a leading part. It is possible that even if such an effort were accepted as desirable and feasible it may become unnecessary and indeed that the whole of the vast structure which has been built up in the United States may yet be abandoned having served its turn. Chemotherapy having conquered in the sphere of streptococcal infection, is turning its attention more seriously to the pneumococcus and it is reported by Whutby<sup>5</sup> that an entirely new sulphonamide compound—2(*p*-aminobenzenesulphonamido) pyridine—has a striking curative action on pneumococcal infection in mice. An account by Drs W. A. Oliver and Maxwell Telling<sup>6</sup> of its effect on three cases of pneumonia suggests that this experimental action will be confirmed clinically. But for the fact that experimental results with these drugs have always hitherto

been amply borne out in the clinical field, it would be unwise to be too sanguine but hitherto animal experiment has consistently been followed by therapeutic success. If chemotherapy can equal or even approach serum treatment in efficacy serum will stand little chance of more extended trial. The practical difficulties of pneumococcus typing and of administering serum intravenously will remain considerable, however perfect the facilities for them, the new chemotherapy involves nothing more than the swallowing of tablets. This is speculation rather than prediction, but it is a very real and important question whether the best treatment for pneumonia will ultimately be found in the form of immunotherapy or that of chemotherapy.

### ONCHOCERCIASIS

Onchocerciasis is transmitted by small but viciously biting Simuliidae and is characterized by subcutaneous nodules containing adult filaria the embryos of which migrate radially for varying distances through the skin. If the nodules are in the region of the head the migrating microfilariae may invade the tissues of the eye and give rise to conjunctivitis, keratitis, iridocyclitis, and other lesions, resulting in many cases in blindness. The disease has been known up to the present time only in rather sharply circumscribed areas in Southern Mexico and Guatemala, and in parts of Africa. In America the nodules are generally situated in the region of the head or scalp and since the first description of the malady more than twenty years ago the disease has been associated there with cases of ocular disturbance and blindness. In Africa it was generally held that the nodules tended to occur more on the trunk or limbs than on the head, and up to a few years ago there was little clear evidence that ocular disturbances there were caused by onchocercal infection. Observations to the contrary led to more detailed investigations one of which is summarized in a recent publication by Strong, Hissette, Sandground, and Becquaert.<sup>1</sup> They confirm the growing opinion that ocular onchocerciasis is not uncommon in Africa, and in fact they go so far as to state that in parts of the Belgian Congo and in Northern Rhodesia onchocerciasis is one of the three most important diseases. The sum of suffering attributable to ocular onchocerciasis may be gauged from the figures of only a few workers. Hissette in one village of 150 inhabitants in the North-West Congo, found sixty-eight with ocular disturbances due to onchocerciasis and fifteen of them were blind. Cruikshank<sup>2</sup> states that 4.5 per cent of the population of the Anglo Egyptian Sudan suffer from endemic blindness much of which is due to onchocerciasis and Larumbe<sup>3</sup> reported from Chiapas, Mexico, that of 4,000 cases of onchocerciasis about 500 had developed keratitis, iritis and choroiditis, and 100 were totally blind. Since possible vectors are

widespread in certain areas in the western United States and the disease has shown a tendency to northern migration, it has been suggested that the condition may be spread by infected immigrants from Mexico and become endemic in the U.S.A., but this risk does not seem great. However, as the manifestations of the disease progress slowly, ocular disturbances may be encountered far from the locality of origin in those who have formerly travelled abroad, such cases have already been recorded in Germany, France, Belgium, and in this country. The way in which the eye changes are produced is still a matter of speculation. Toxins from the adult worms or the larvae, particularly at their death, mechanical damage by microfilariae, and allergic reactions from sensitization of the tissues to filarial antigen are among the explanations suggested. Hissette for some days injected extracts prepared from adult worms in the neighbourhood of the eyes, but failed to induce any ocular reactions. In another experiment in which microfilariae were introduced into the cornea the corneal microscope and the slit-lamp revealed not the slightest irritation along the course followed by the larvae in the cornea over a period of some days. It is of course not possible to draw any conclusions from these early and isolated observations. As to treatment, removal of nodules presumably containing the parturient parasites may arrest the progress of the disease. Sometimes, however, this fails, perhaps owing to the presence of unencapsulated worms or the existence of undiscovered nodules. In some regions of Africa cases may have a hundred or more nodules, although in Central America and many parts of Africa it is usual to find cases with only comparatively few nodules. The destruction of the parasites by drugs has also been attempted but the results are unsatisfactory as an efficient filaricidal drug has not so far been discovered.

### RADIUM METABOLISM

The effects of stored radium salts in human beings appear to be wholly pernicious. Storage occurs chiefly in the bones, so that the main effects have been necrosis of the jaw, severe anaemia and osteogenic sarcoma. The study of radium metabolism is of much academic interest, and of some practical importance, seeing that cases of poisoning by radio-active substances are likely to occur for some years to come. Thus of the three cases recently reported by J. C. Aub and his associates<sup>4</sup> one had been given radium intravenously ten years before as treatment for chronic arthritis, the second was a dial painter, and the third was a physicist who had inhaled some radon accidentally. In the acute stage, during the first few months after exposure the radium is scattered throughout the body and rather loosely held. Excretion is at first rapid as much as 90 per cent of a quantity of radium taken by mouth being excreted within the first week. Gradually the remaining radium is stored preponderantly in the bones so that the rate of excretion falls. Radium thorium B, and polonium like lead, are at first stored largely in the bone trabeculae but slowly the abnormal metal becomes dis-

<sup>1</sup> *Summary to Amer. J. Trop. Med.* 1938 18 No 1.

<sup>4</sup> *Aust. J. Trop. Med.* 1938 11 1443.

imbuted equally between trabeculae and cortex. As the cortex is far heavier than the trabeculae most of the radium is stored in the cortical bone and excretion becomes very slow in chronic cases amounting to only 0.1 per cent of the total stored radium per month. The main route of excretion of stored radium is in the faeces but as with lead what part of the intestinal tract is involved is not well known some however is certainly excreted through the bile. The rate of excretion can be increased four to eightfold by decalcifying therapy or de-leading therapy as it has been called. A period of high calcium intake is followed by a period of low calcium intake together with parathyroid extract, thyroid extract and ammonium chloride. The response of radium excretion is slower than that of calcium but more prolonged. By estimating the Ca/Ra ratio in the bones it is found that decalcifying therapy is no more efficient in extracting radium than in extracting calcium from bone for both are excreted in their relative proportion in the body. The difficulty indeed is not so much getting the radium out of the bones into the blood stream as in getting it out of the blood into the excreta for the daily radium elimination is only slightly greater than the total radium content of the blood at any moment of the day. The increased excretion of radium still does not greatly reduce the total store of radium in the body and in chronic cases when it is probable that the cells where radium is stored have been injured the response to medication is even less effective. Nevertheless in one of Aub's patients who had had a severe necrosis of the jaw of two years duration the bone healed following therapy and has remained healed for two years in spite of the fact that only a small percentage of the total radium stored in her body was eliminated during the course of treatment.

## MEDICINE AND NATIVE HEALTH IN KENYA

An exhibition illustrating African progress and activity in Kenya was opened at the Imperial Institute London on Monday by the Duchess of Gloucester. The exhibition for which the Kenya Government is responsible has considerably greater interest for the medical profession than would perhaps appear from its title in that it not only contains a specifically medical section but is based throughout on the conception that only through education and a raising of the standard of rural life in the Colony can the health of the native population be permanently improved. 'Without good agriculture the catalogue states 'ill nourishment a greater cause of ill health in Africa than perhaps any other will never disappear. The reclamation of a papyrus swamp for the growing of rice is consequently shown to have medical significance equally with the training of natives in skilled labour of many kinds and the replacement of native huts by native houses and cottages. The pictures in the medical section proper illustrate the work among other institutions of the native hospital at Kiambu, the mental hospital at Nairobi and the medical research laboratory also at Nairobi. The Kiambu Hospital is taken as being typical of a group of seventeen hospitals in native

reserves. It has fifty beds for medical and surgical cases and twelve beds for maternity cases and with this accommodation serves a population of 100 000. It is interesting to notice that the maternity ward was provided by the local native council out of local funds. Judging from the unusually interesting series of photographs which are shown excellent progress is being made in training native laboratory assistants at the central Nairobi institute to perform such duties as the identification of mosquitos and the preparation of plague and other vaccines. Plans are at the present time maturing for the construction of a new Central Hospital which will ultimately contain about 1 000 beds for native patients. The first part of the hospital is expected to cost about £130 000 towards which £50 000 has already been allocated. The completion of this hospital will in conjunction with the existing Central Laboratory offer exceptional advantages for clinical research. It is also intended to use the hospital for the systematic training of native girls in general nursing to assist the European nursing sisters. Hitherto men have been chiefly employed apart from maternity cases. In addition to the institutions already mentioned there are seven hospitals for Africans in the towns, two hospitals for infectious diseases, two leper hospitals, three hospitals for Europeans, a number of general wards for patients of Asiatic origin and half a dozen other smaller hospitals. There are also more than 200 out patient dispensaries chiefly in the native reserves. In 1936 more than 14 000 operations were performed on African natives alone.

## HOUSING AND PLANNING

The mass of evidence shows that the British housing problem has been cruelly oversimplified. Good housing is not the absence of slums any more than good health is just the absence of disease. Slum clearance in Britain is not merely a question of the substitution of a clean box for a dirty one. It is not a problem that can be solved by better planning.

These sentences are from *Europe Re housed* by Elizabeth Derby, one of the most useful and suggestive books that have lately been written on the general question of housing for the non technical reader and from the wider point of view implied by that quotation. The author after eight years experience of housing and slum clearance in London was enabled by a Leverhulme Research Fellowship to spend a year in ten European countries studying the methods and results which they had adopted or achieved in this field since 1918. In fact she chooses six of these countries for discussion and illustration—'two winners in the war, two neutrals and two losers'—France, Italy, Sweden, Holland, Germany and Austria (or Vienna). The national variations of the housing problem and of the methods of dealing with it are set out in a most interesting fashion and are illustrated by a considerable number of appropriate diagrams and photographs. The lessons for Britain are forcibly and effectively stated. As has been indicated emphasis is laid much more on the amenities within the home and amenities on the planned

<sup>1</sup> George Allen and Unwin 1s. 6d.

estate outside the home than on architectural or legal requirements in the structure itself. The results of these comparisons are striking and not flattering to this country. Great Britain has spent vastly more money per dwelling and far larger sums in total than any other country, but a great deal of this has been extravagant or wasteful and if all-round value for money is to be the test the author would place Vienna first and Sweden second in the order of success. There are reasons which account for this order and for these variations of style and method. They are expounded in the book, and in her final chapter and conclusions the author eloquently drives home the need for a clarification of the view usually taken in Britain and for a vigorous adoption of a most enlightened policy to take advantage of an opportunity which is not yet quite lost. Proper housing and civic planning are now among the major sociological problems and are manifestly and intimately connected with national health and fitness. It is not a mere question of convenient shelter, but rather, as the author points out of "satisfying the incipient demand for healthier conditions greater convenience, and pleasure in the environment of townspeople." As Lord Horder says in a foreword "It is always a satisfaction, when approaching any question of deep human interest to know that the guide is both expert in technology and experience and yet gifted with vision. Both of these assets are here."

### "DENTAL BENEFIT"

Test meals are commonly regarded as unappetizing concoctions of gruel, charcoal, or alcohol lacking in essential oils, by which the stomach is put through its paces and sometimes jerked to even greater feats of secretion by injections of histamine. If Mr Samson had his way a test meal with a difference, would be diagnostically applied to his patients by the dental surgeon. Writing in a recent number of *Wine and Food*<sup>1</sup> he deplores the mental anguish of the sufferer while the dentist prospects with pick and mirror and searches out those nooks and crannies so ready to react to painful stimuli. How much better it would be to combine pleasure with pain and to observe the dental patient's reaction to a skilfully planned luncheon! The "menu de dents" is Melon Canteloup au Marasquin, Lobster Mayonnaise, Cotelettes d'Agneau au Concombre Glacé à l'Eau aux Framboises, Canape Fedora. The effects of this delicate repast on the patient are watched with notebook and concealed stop-watch. The iced melon causes a wince and a pause in mastication until the food has warmed. "Exposed nerve, sensitive to cold left eye closed, indicates decayed tooth on same side" runs the anamnesis. The fibres of the lobster lodge in the cavities between the teeth only to be recovered by much sucking and tongue-twisting or the use of a toothpick. The stop-watch comes into play with the cutlet and cucumber, delay in mastication or gulping indicates loose teeth or ill opposed ones. The raspberry water-ice reveals the poorly fitting denture with a sudden leap as the pips get under the plate, this is followed by cautious chewing and gulping of the

fruit, and at the same time the coldness of the ice reveals that the receding gums are hypersensitive to cold. The savoury departs from the orthodox recipe as the olive is left unstoned on its bed of bacon and mushroom, and to strip the flesh completely from the stone without the aid of fingers indicates a full complement of concerted teeth. So ends the dental diet. Diagnosis is complete and remedial measures may be begun, but to dull the pain of these Mr Samson advises that the meal should be preceded by several glasses of sherry and accompanied by a bottle of red burgundy. Gastronomically this is hardly correct and may require a subsequent visit to a gastro-enterologist, but, as he says "the patient will soon emanate a kind of roseate aura of benevolence and comfort akin to that produced by the best type of anaesthetic and submit to the most violent form of treatment with only a faint grimace."

### LIVE VACCINES FOR GONORRHOEA

Chronic gonorrhoea in women, especially when it involves the deeper layers of the cervix uteri and the adnexa, is notoriously a difficult and unsatisfactory condition to treat. It is doubtful if even those antiseptics which are said to penetrate beneath the surface ever reach the gonococci buried in the cervical glands. In a case in which the cervix of a woman who had had gonorrhoea was removed sections showed below the mucosa yellowish spots from which pus exuded, examination of this pus revealed gonococci in smears and cultures. Histological examination showed the cervical glands covered with squamous epithelium in manifold strata and the musculature was infiltrated with round cells and plasma cells. It is obvious that locally applied antiseptics can have no effect on such lesions, while on the other hand the various forms of cauterization recommended by different workers to be effective in killing all the gonococci must destroy tissue as well. As far back as 1922 Loeser<sup>2</sup> injected killed vaccines into the cervical tissues and found these much more effective than vaccines given in the ordinary way, but even so results were not satisfactory. He now believes that true immunization is only obtained when living active gonococci are injected into the skin. Numerous strains of gonococci from fresh untreated cases are grown on ascitic agar. A subculture (not later than the fourth) forty-eight hours old is washed off the plate with 3 c.c. of a sterile isotonic salt solution. The suspension which should contain 8,000 to 12,000 million organisms is shaken and 1.5 c.c. are injected into the skin of the patient's left upper arm, forming two or three wheals. "Slimy" cultures are better than "flaky" ones. To prevent pyrexia salicylates are prescribed. Two more such injections each of 3 c.c., are given at intervals of seven days. If fresh live cultures are not available, a preparation known as "gonovitan" (Sachsische Serumwerke, Dresden) may be substituted. Usually the gonococci tend to disappear from the discharge immediately after the first injection but they may show a temporary increase before finally disappearing after eight to twenty-one days. The experi-

<sup>1</sup> *Wine and Food* 1938 17, 8

<sup>2</sup> *Brit J Venere Dis* 1938, 14, 42

cases of thirty nine workers who give 10 102 injections to 3000 men and women are quoted. The average proportion of cures was 80 to 85 per cent. The results are particularly good in chronic gonorrhoea in cervical gonorrhoea with ascending infection and in affections of the joints and tendon sheaths. The treatment is of no great value in acute urethritis. Harmful effects were negligible and amounted to only 0.06 per cent. most of these consisted of abscess formation which may have been due to other organisms. The principal point about this treatment is that it is the skin which plays a powerful part in the development of immunizing bodies. This has been realized by others notably Lambkin and Dimond who recommend that their ecto antigen should be given intracutaneously. Most venereologists will welcome any method which holds out good hope of success in the treatment of chronic cervical gonorrhoea especially if it is harmless and easy to apply. If the occurrence of complications is feared the patient may be given a preliminary dose of 0.3 ccm. The only practical difficulty is the source from which the live vaccine is to be obtained. In a clinic with a laboratory attached material may be always available but in private it would probably be best for the clinician to obtain a fresh polyvalent culture from a laboratory and add the necessary saline himself withdrawing the suspension direct from the plate with a syringe and injecting at once. Live vaccines certainly seem worthy of trial. Judging from the literature they appear to have been hitherto little used in this country.

### MODE OF ACTION OF DIGITALIS

Few drugs have been investigated more extensively than digitalis but the manner in which it produces certain important clinical effects is still obscure. The dramatic result obtained by digitalis in auricular fibrillation can be reproduced in laboratory experiments and has been satisfactorily accounted for but it is more difficult to explain the clinical improvement effected in cases with a normal cardiac rhythm. Digitalis was shown by Cushman to augment the activity of the mammalian heart under certain conditions and recently McKen Cattell and Gold have demonstrated the beneficial action on isolated strips of muscle from the cat's heart of ouabain in dilutions of even one part in seventy millions—which is equivalent to the concentration probably achieved therapeutically in man. Similarly digitoxin diluted to one part in ten millions had a powerful augmentor effect. These results indicate one possible mode of action of digitalis on hearts with a normal rhythm but other laboratory evidence suggests that in such cases the drug affects the peripheral vascular system rather than the heart. Most workers are agreed that in the intact animal digitalis decreases the minute volume the size of the heart and the venous pressure. It is difficult to account for these manifestations by any direct cardiac action and Dock and Tainter suggested that the drug caused a constriction of

the hepatic veins with a consequent pooling of blood in the liver. The problem has been investigated by Katz and his co workers who conclude that in therapeutic doses digitalis (digitofoline) affects the heart only indirectly its primary action being on the sphincter of the hepatic vein and on other blood vessels of the liver. This pools the blood in the splanchnic area and thus decreases the venous return to the heart and the size of the heart. The chief action of toxic doses however is they conclude directly upon the heart. Digitalis is generally recognized as by far the most important drug available for the treatment of cardiac disease but the simultaneous appearance of two papers pointing to such divergent conclusions does indicate that our knowledge of its mode of action is still very imperfect and that this action is probably more complex than has been thought.

### THE HEBERDEN SOCIETY AND ITS MEDAL

The Heberden Society was formed as a committee for the study of rheumatism about two years ago. Its membership includes all the medical staff present and past working at the British Red Cross Society's clinic in London and a limited number of other workers interested in the study of rheumatic diseases. Meetings are held quarterly or more often to discuss lines of research read papers and show cases. As the

name "Heberden" is always associated with one of the manifestations of rheumatism it seemed an appropriate and euphonious title for a group of workers in that field. The society has now instituted a Medal to stimulate research into the causes and incidence of rheumatic diseases. This will be awarded yearly for the best work done in that direction and the recipient will be invited to deliver a Heberden Lecture. We reproduce the obverse of the Heberden Research Medal. The honorary secretary is Dr Kenneth Stone 58 Chesterfield House Mayfair W1 to whom inquiries should be addressed.

Dr E. H. Cluver, Director of Medical Services, Union Defence Force and Deputy Chief Health Officer, has been appointed Secretary for Public Health and Chief Health Officer for the Union of South Africa in succession to Sir Edward Thornton who is retiring.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## MINOR DENTAL EMERGENCIES IN GENERAL PRACTICE

BY

G. G. EXNER, M.R.C.S., L.D.S.

As most of the diseases of the jaws arise from the teeth and the hard and soft tissues surrounding them a general knowledge of their anatomy is important, a cross section of a tooth *in situ* is therefore given below (Fig 1)

FIG 1—Cross section of a tooth *in situ*

### Pathological Conditions

Decay is the breaking down of the prisms of enamel of the crown of a tooth. Foodstuff collected on or between teeth ferments, and in the process of fermentation an acid is produced which dissolves the interprismatic substance holding the prisms together. The latter breaks down and a cavity into the tooth ensues. This may progress into the dentine and lead eventually to the destruction of the pulp. It is also believed that a metabolic form of caries exists, due to deficiency of the calcium which is necessary for hard and resistant teeth. This view is supported by the occurrence of the pregnancy type ("white") caries, in which the internal dentine structure breaks down before a flaw appears in the surface enamel.

Toothache may arise from two factors (1) pulpitis, and (2) periodontitis. It ensues when the decay reaches deep into the dentine, which shows nerve endings in its substance. Irritation of the latter, due to the progressing decay, causes a pulpitis, or irritation of the pulp, which is the so called "nerve" of the tooth.

### Pulpitis

The pain of pulpitis is throbbing and intermittent, thermal changes, especially heat, cause pain owing to the expansion of inflamed tissues within the solid walls of the tooth. Cold at this stage gives relief, as it constricts the tissues. Tapping of the tooth causes no pain. This is important in distinguishing pulpitis from periodontal inflammation, which is dealt with below.

Sedative dressings of oil of cloves, carbolyzed resin, or eugenol inserted into the carious cavity on a pledget of cotton-wool usually give immediate relief. If no relief results the pulp must be removed. When the pain abates the cavity should be cleaned of all decayed substances and

then filled with some replacement material. If the disease has progressed too far the pulp dies and disintegrates resulting in the formation of an abscess at the apex of the root.

### Periodontitis

This is an inflammatory condition of the periodontal membrane, a thin fibrous membrane which surrounds the tooth and which can be likened to the periosteum of bone. Its fibres sling the tooth into its bony surroundings and therefore act as a cushion or buffer during mastication. Inflammation and swelling of this membrane force the tooth from its socket, and the patient will complain of the tooth being too long. Pressure and tapping on the tooth are very painful. The pain is dull and constant, but is not evoked by thermal changes.

The condition may arise from two causes.

(a) *Trauma*—When this arises from a blow on a tooth counter-irritants such as aconite and iodine are best applied to the gum around the tooth for twenty-four to forty-eight hours. If no relief results, or the pain gets worse, extraction is indicated.

(b) *Degeneration of the Pulp*—This may cause inflammation of the periodontal membrane, in which case the tooth should be opened, the pulp removed, and drainage established. Again if no relief is obtained the tooth should be extracted.

### Neuralgia

This may be local or be referred by either a pulpitis or a periodontitis. Certain teeth affect certain areas (see Head's classification). The pains are always associated with a tooth or teeth on the same side of the head as the neuralgia. Referred pains never cross the midline. The offending tooth should be treated or, if no relief is obtained, removed.

### Extractions

For straightforward extractions two pairs of forceps only are necessary. For the lower jaw a pair of "duck-

FIG 2—Duck bill and universal forceps used for removing lower and upper teeth

'bill' forceps are required, and for the upper jaw a "universal" pair (Fig 2). For the actual removal, be it of tooth or root, it must be remembered that one blade of the forceps is inserted buccally or labially and the

other blade will automatically follow on the palatal surface in the upper jaw and the lingual surface in the lower jaw.

The secret of extraction is to drive the forceps as high or as low as possible (depending on whether it be the upper or the lower jaw) and then to close the forceps until a good grip of the tooth or root is obtained. Once the tooth has been firmly gripped the correct movement of dislodging it is undertaken. This latter varies with almost every tooth but it is of the utmost importance to remember that *pressure should be maintained towards the apex of the tooth throughout the extraction*. The idea of this is to make the apex the fulcrum otherwise the crown or part of the tooth fractures. The operator stands in front of the patient for the removal of all teeth except those in the right lower jaw when he stands behind and to the right. The left hand should always be used to hold away the lip or cheek with one or two fingers and to guide the forceps into position (Fig. 3). In the case of the lower teeth the left hand is used to support the jaw. The left lower teeth are removed by placing the index

wards. In other words a to and fro movement should be employed (Figs. 4 and 5).

**Lower Premolars and Canines**—These teeth have conical roots and rotation is indicated.

**Lower Incisors**—These have roots flattened on their medial and lateral sides and only a to and fro movement towards the tongue and then outwards should be undertaken.

**Lower Wisdom Teeth**—These are of especial interest as their position is so far back that removal by forceps is not always easy or even possible. Furthermore the roots often tend to curve back sharply, and their removal is

FIG. 3—Position of operator's hands for removal of upper teeth.

FIG. 4—Position of operator's hand for removal of left lower teeth.

finger into the sulcus, the middle finger on the lingual side and the thumb below the horizontal ramus of the jaw. This gives a grip and the necessary support to the mobile lower jaw during the extraction (Fig. 4). The right lower teeth are removed by supporting the jaw with the whole hand, the thumb being placed on the lingual aspect, the index finger into the sulcus while the rest of the fingers and hand support the horizontal ramus and the operator stands behind and to the right of the patient (Fig. 5).

FIG. 5—Position of operator's hands for removal of right lower teeth.

#### INDIVIDUAL FORCEPS MOVEMENTS

**Upper Molars**—As these are three rooted teeth the movement of the forceps is outwards (Fig. 3).

**Upper Premolars**—The first premolar has bifid roots and the movement should be only outward. The second premolar is single rooted, and slight rotary movement can be applied at the same time as the outward movement.

**Upper Canines and Incisors**—These are conically rooted teeth and rotation and an outward movement should be combined.

**Lower Molars**—These are two rooted with anterior and posterior roots that are flattened on these aspects. The movement is inward towards the tongue and then out-

FIG. 6—Straight lever used for removing wisdom teeth.

FIG. 7—Right and left right angled levers used for removing roots.

therefore much more easily undertaken with a straight elevator or lever (Fig. 6). The lever has two surfaces rounded on one side and flattened on the other. The point is inserted and driven downwards between the second and third molars with the flat surface against the third molar or tooth to be removed. The lever is then bent downwards and the point engages against the surface of the anterior root of the tooth to be extracted, the second molar and the outer alveolar plate being used as a fulcrum. The second molar can well be removed by the same procedure. Two levers are necessary, one for the left and one for the right hand side.

#### Complications of Extractions

**Fractured Roots**—These occur most frequently in the lower jaw. If an empty socket is present next to the root its removal is undertaken by inserting the right angled

FIG. 8—Lever to remove root.

elevator (Fig. 7) into the empty socket and twisting it so that its point penetrates the septum or intervening piece of bone and engages the root which is then easily displaced (Fig. 8).

**Fractured Alveolus**—If a piece of bone is fractured during extraction it is best removed

**Fracture of the Mandible**—As a temporary measure a four-tailed bandage should be applied to the jaw and held in position until the splints have been made and the jaw set and splinted in the correct position

**Septic Socket**—Wash out with hydrogen peroxide and then follow with some mild antiseptic solution. If very painful a "dry socket" has occurred, and this is usually due to the sequestrum of bone between the roots having become necrotic. It is advisable to remove this, and when the socket has been syringed out a sedative dressing, in the form of a light tampon dipped in "dentrolone," should be inserted. If the socket is too painful to treat, pain is best relieved by the insertion of a 5 per cent or 10 per cent solution of cocaine. The wound should then be cleansed and a dressing inserted.

**Haemorrhage**—Primary and reactionary haemorrhages are treated in the same way. Reactionary haemorrhage usually starts several hours after the extraction. The clot should be removed and the socket syringed out with a mild hot antiseptic solution. Plugging is then undertaken with a strip of gauze dipped in a 1 in 1,000 adrenaline solution or oil of turpentine, or one of the modern drugs, such as sangostop, or snake venom from the Russell viper, which appears on the market under the proprietary name of stypten, can be used. The socket is replugged in twenty to thirty minutes if the bleeding has not ceased. In the case of haemophiliacs a local styptic is always indicated, and if bleeding is not brought to a standstill within a few hours a blood transfusion may have to be undertaken. Blood grouping, etc., should have been performed before the operation, and all arrangements made for an emergency.

**Secondary Haemorrhage**—This is rare, and is always associated with sepsis. Its treatment is the same as that for primary haemorrhage. After the septic material has been removed and the cavity thoroughly irrigated replugging should be done frequently to prevent the further accumulation of septic material. Bone infection must be watched for as a likely possibility.

**Dislocation of the Mandible**—This occurs more often than is usually supposed, and is especially liable to happen when extractions are done under a general anaesthetic. The dislocation may be unilateral or bilateral, the treatment being the same in either case. The thumbs are placed over the lower molars and the mandible forcibly depressed and pushed backwards. If the reduction does not occur—and this is rarely the case—the patient must be completely relaxed under a general anaesthetic. The dislocation is then easily reduced.

**Root Driven into the Antrum**—If the patient is seen shortly after the penetration of the root into the antrum the opening is enlarged and the root is readily removed by plugging the antrum with long strips of gauze and gently pulling it out again. Invariably the root comes out with the gauze, although the process may have to be repeated several times. The hole in the antrum is closed by dissecting up the mucous membrane from the sulcus until a serviceable flap has been obtained. This is drawn over the hole and sewn to the palatal mucous membrane.

**Root in the Antrum with Acute Infection**—Drainage must be established. Usually a probe inserted into the tooth socket will allow the pus to escape. This gives instant relief and converts the acute case into a chronic one. After a day or two the antrum can be washed out via the tooth socket. This is repeated several times,

if necessary, and then the same operation is undertaken as that described for the removal of a freshly fractured root in the antrum. It is advisable, however, to make an opening between the antrum and the nose, below the inferior turbinate bone, to establish free drainage, before closing the wound between the antrum and the mouth.

**Treatment of an Acute Abscess**—The patient usually appears with a swollen face, the size of the swelling varying considerably. Sometimes it is localized over the apex of the tooth only, or it may be very much more diffuse. Treatment consists in the establishment of drainage. An incision is made into the abscess under general anaesthesia (gas), or the surface of the swelling is frozen with an ethyl chloride spray and the scalpel inserted. The incision should be made as near the tooth as possible—namely, into the muco-periosteum, and not into the cheek or its soft structures (Fig 9). This prevents profuse

FIG 9—Incising an abscess

bleeding or the possibility of carrying the infection deeper or of incising some important structure. The offending tooth should be removed a few days later. If it is loose and accessible (in contradistinction to a deeply buried root) it can be removed at the same time as the incision is made. In single-rooted teeth an incision with drainage of pus relieves the condition, and after the acute symptoms have subsided treatment of the tooth can be undertaken, and it can be saved—a useful entity. This is especially important in the case of young girls and children who have a more or less perfect complement of teeth, and in whom the loss of one incisor tooth would result in a great aesthetic blemish.

M L-M Pautrier (*Ann Derm Syph Paris*, January, 1938) points out that lupus pernio of Besnier, sarcoids of Boeck, and small fibrotic lesions in the lung are probably all manifestations of a single reticulo endotheliosis, and that although the condition is only recognized by dermatologists because of the skin lesions there are cases in which the lung and glands are affected without any skin manifestations. He describes the case of a small boy, aged 10 suffering from spinal caries, who developed subcutaneous nodules near the affected area, which, on microscopical examination, showed a large number of giant epithelioid cells surrounded by lymphocytic infiltration. Later cystic rarefactions were demonstrated at the base of the phalanges, diabetes insipidus developed, and finally after a number of years, lupus pernio. The author recalls a case of diabetes insipidus reported by Tillgren, in which there was generalized adenitis with enlargement of liver and spleen, and many epithelioid nodules and cells demonstrable on microscopical examination. Pautrier reports, too, a case in which an apparently fit man requested removal of cervical glands which had been enlarged for many years and only worried him on account of their appearance. He was found, on further examination, to be suffering from generalized adenitis and enlargement of the spleen, and typical giant epithelioid cell collections were found on biopsy.

## THE LISTER INSTITUTE ANNUAL REPORT

On June 2 the Lister Institute of Preventive Medicine published its forty fourth annual report. We give here a brief review of some of the work done during the past year and recorded in the report.

### Virus Studies

Dr G H Eagles and his collaborators have continued their work on the agglutination by serum from cases of haumatic fever and rheumatoid arthritis of suspensions of virus like bodies obtained from similar cases. Positive agglutinations were observed considerably more often with such sera than with sera from patients suffering from other infections of joints: positive reactions were especially frequent during first attacks of rheumatic fever or rheumatoid arthritis.

Dr M H Salaman has confirmed Craigie's finding that the elementary bodies of vaccinia virus contain a heat stable and a heat labile antigen. Elementary bodies treated in the cold with the least amount of formalin which would render them non infective retained the heat labile antigen and a part of their power to absorb virus neutralizing antibody which property was destroyed by heating or treatment with alcohol. A lowered infectivity was brought about in elementary bodies by treating them with antiserum and then separating off the antiserum by centrifugation and washing. Dr Marjorie G Macfarlane has found that suspensions of vaccinia virus contain phosphatase and catalase in relatively large amounts. Studies by Dr A S Macfarlane and Mr R A Kekwick suggest that the particles of this virus need a water envelope for their stabilization and that salts cause flocculation by removing the water. Dr D McLean is investigating in nurses the possibility of producing immunity by the intracutaneous injection of a suspension of elementary bodies.

### Serological Studies

Dr A Felix and Miss R Pitt have found that the inactivation by phenol of the immunogenic function of the Vi antigen of *Bact. typhosum* seems to be due to some type of reversible reaction: the phenol can be removed and replaced by fresh saline with restoration of the immunogenic property. The search for a sterile antigen which could be used instead of living bacilli in the preparation of anti typhoid serum in horses for therapeutic use in man has been continued by Dr Felix and Dr G F Petrie. The position remains much the same and the bacilli are still the indispensable source of the "natural" Vi antigen required for the elaboration of the Vi antibodies. It has been observed however that the "denatured" Vi antigen present in whole bacterial cells after chemical treatment will induce an abundant Vi antibody formation in the rabbit though not in the horse. Dr W T J Morgan has obtained by diethylnegylcol extraction substances corresponding to the Vi and O antigens apparently free from proteins and capable of producing an antigenic response in the horse and rabbit but the immune body produced by this Vi antigen is less effective in protection experiments than that produced by suspensions of living bacilli. Dr D W Henderson has shown that twenty to fifty times more antibody may be needed to protect mice against relatively avirulent strains of *Bact. typhosum* than is the case with fully virulent strains, suggesting that the degree of virulence is of far less significance in this respect than is the total amount of antigen which requires to be neutralized.

Dr Felix has obtained further evidence of the value of the Vi agglutination reaction in the serological detection of chronic typhoid carriers: he was also partly

responsible for recommendations on the standardization of the Widal reaction which have since been adopted as a provisional international standard.

Dr H L Schutze has shown that the envelope antigen of *B. pestis* is the determining factor in prophylactic vaccination in the white rat and can be developed equally well by both virulent and avirulent strains and both rough and smooth varieties. Dr P A Gorer with Dr Schutze has been able to correlate H antibody production for *S. typhi murium* with resistance to infection with this organism in highly inbred mice. By brother-sister inbreeding for over thirty generations a pure mouse line has been obtained with a remarkable uniformity of reaction to infection. The value of such a line in laboratory experiment and in the standardization of biological products is obvious.

Work on the standardization of therapeutic sera has proceeded with particular regard to Type I anti pneumococcus serum and tetanus antitoxin. An interesting finding is that the therapeutic effect of an intravenous injection of tetanus antitoxin varies with the time interval between the injection and the previous administration of lethal doses of toxin: some effect is apparent even with injection at a time representing one third of the survival period of untreated control animals.

### Endocrinology

Dr V Korenchevsky contributed an article on the bisexual properties and co-operative activity of sexual hormones to this *Journal* last year (1937 2 896). His work on this subject using rats as experimental animals has been continued with the assistance of Miss K Hall and Mr R C Burbank. Antagonistic as well as co-operative activities are now being studied—for example the suppression by progesterone, testosterone, or androstenedione of the cornifying effect of oestrogens. During the pro-oestrus phase it has been noted that while the deeper layers of the vaginal epithelium are cornified as in oestrus the superficial cells become large and lucid resembling mucous cells: these changes have been termed pseudomucous metaplasia. Changes in the uterus and vagina in the prolonged resting phase (dioestrus) commonly occurring in the winter months and remanent of slight pregnancy changes were shown to be the same as those produced by the administration of small doses of progesterone and oestrone. Large doses of progesterone and very small doses of oestrone caused changes in the sexual organs histologically identical with those of pregnancy but the size and weight of the organs remained much less than during pregnancy. Better development was obtained when testosterone and other male hormones were also administered. Large doses of oestrogens it was found antagonize and suppress the pregnancy changes produced by progesterone. Another effect of large doses of oestrogens is the production of a uterine epithelial metaplasia which may become carcinomatous: this effect is suppressed by the simultaneous administration of progesterone. Large doses of male hormones are also dangerous in that they cause in the adrenals of males marked pathological changes.

### Vitamin Studies

A large scale investigation organized by Miss E Margaret Hume has given results in substantial agreement with the conversion factor of 1600 adopted in 1934 by the International Conference (League of Nations) on Vitamin Standardization connecting results of vitamin A assays by biological and spectrophotometric methods respectively. It has also shown that the value of 3000 international units of vitamin A per gramme previously ascribed to the U.S.A. reference cod liver oil is too high, the exact figure is more nearly 2600 I.U. per gramme. Equally extensive has been a biological investigation of

the potency of synthetic crystalline vitamin B<sub>1</sub>. Work done at twenty-two laboratories, the results being pooled and averaged, shows that 3  $\mu$ grammes of the crystalline material may be regarded as equivalent in potency to one international unit (10 mg of the adsorbite on fuller's earth of an extract of rice polishings).

Dr A R Todd and Dr F Bergel, after their synthesis of vitamin B<sub>1</sub>, have continued a study of the synthetic analogues of aneurin. With certain bacteria—for example, *Staphylococcus aureus*—the pyrimidine and thiazole derivatives of which vitamin B<sub>1</sub> is now known to be composed, when presented separately, had a growth-stimulating effect equal to that of vitamin B<sub>1</sub>. The vitamin B<sub>1</sub> complex has been shown to be concerned in some way with tissue-oxidation processes. Attempts have been made by Dr T F Macrae, Miss Constance E Edgar, and Dr M M El Sadr to purify the two dietary essentials other than lactoflavin in autoclaved yeast extract. Neither of these factors can be replaced by nicotinic acid imide in the nutrition of the rat, though nicotinic acid amide is present in one of them—the yeast eluate fraction of the vitamin B complex. This fraction, according to Sir Charles Martin, Dr Harriette Chick, and Dr A P Martin, will maintain in health pigs fed on the maize pellagra producing diet, which, in the absence of this small daily supplement of yeast eluate fraction, gives rise to a severe nutritional disease.

Nicotinic acid which has a curative effect on human pellagra the "black-tongue" of dogs, and the corresponding nutritional disease of pigs, has been shown in rats to be either inessential or necessary only in quantities small enough to be supplied even by the maize dietary which causes such severe disturbances in pigs and dogs. Dr P Ellinger, with Professor Ali Hassan and Mr M M Taha, obtained promising results in the treatment of Egyptian pellagrins by the administration of lactoflavin with the eluate and the filtrate obtained after adsorbing autoclaved aqueous yeast extract with fuller's earth. Dr Ellinger also noted in a group of seventy patients the association with pellagra of porphyrimuria and parasitic infection of the gastro-intestinal tract. This work was exhaustively reviewed in a leading article in the *Journal* of January 15 (p 127).

Dr S S Zilva has studied the alleged antitoxic properties of L-ascorbic acid in diphtheria. Groups of guinea-pigs subsisting at vitamin C levels ranging from almost complete depletion to supersaturation were given 1 to 2 minimum lethal doses of diphtheria toxin. The course of the toxæmia and the length of time before death ensued was the same in all the various groups. Dr Zilva has also shown, with Dr F Kidd and Dr C West, the gradual alteration in the balance of L-ascorbic acid and dehydro-ascorbic acid brought about during the growth of apples by an enzyme identical with the apple phenolase. Attempts are now being made to increase the vitamin C content of canned apples by the addition of an extract made by boiling and pressing the peel. Other work by Dr Zilva seems to suggest that the "vitamin P" activity (alteration in vascular permeability) observed by Szent-Gyorgyi and his collaborators may have been due to contamination of the crystalline substances obtained from lemon juice, with which they worked, by traces of L-ascorbic acid.

Drs A R Todd, F Bergel, T S Work, and H Waldmann have elaborated a process yielding from wheat-germ oil concentrates which show full vitamin E activity in a dosage of 15 mg. They have also isolated pure  $\beta$ -tocopherol, a nearly colourless oil showing full vitamin E activity in rats in doses of 3 to 5 mg. Routine biological testing of vitamin E preparations has been carried out by Miss Alice M Copping since April, 1937.

It is impossible to mention all the other activities of the Lister Institute, but its report is a document worthy of study indicating as it does the recent trends in several of the more important departments of modern research.

## LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

The annual meeting of the London and Counties Medical Protection Society was held at Victory House, Leicester Square, London, on June 8. Sir CUTHBERT WALLACE, Bart, who presided, referred to the loss which the Society had sustained in the deaths of Sir Squire Sprigge, a vice president, and of Dr R L Guthrie, treasurer, and in the retirement of Dr C M Fegen, one of the founders of the Society and until lately its secretary. He also welcomed the new secretary, Dr R W Durand.

### Review of a Year's Work

Speaking of the year's work of the Society, Sir Cuthbert Wallace said that of its nearly 16,000 members 10 per cent had occasion during the year to seek the Society's advice or assistance in one form or another. An important point to remember was that municipal hospital authorities were now insisting that their medical officers should join a protection society. There could be no evasion of personal responsibility on the part of such officers. The need for protecting their interests was exemplified during the recent Croydon typhoid inquiry, for had the Society not undertaken the defence of its member Dr Holden, M.O.H. for Croydon, he would either have had to arrange for his own representation and bear the heavy burden of expense entailed or to go unrepresented. Sir Cuthbert Wallace again mentioned the desirability of having radiographs taken in all cases of suspected fracture, or, if the patient refused to be x-rayed, of having an authentic record to that effect. Another very important thing the lack of which frequently embarrassed the Society in taking up cases for its members, was the keeping of proper records. He sympathized with the doctor who was impatient of records, they had been the bane of his own professional career and he had often said to his students, "There is nothing hard in medicine or surgery the only hard thing is to get the truth out of a patient." But records were necessary, among other reasons, having in view the protection of the doctor in subsequent contingencies. It seemed scarcely necessary to urge accuracy in certification but the experience of the Society showed that many practitioners were tempted by good patients and their own good nature to give certificates which economized the truth, they should remember that the members of the medical profession had to serve not only their patients but the public. Finally he mentioned that the Society had received many applications from practitioners overseas asking for a similar protection to that accorded to their colleagues in the home country, and the council was exploring the situation.

### Financial Position

In presenting the financial report Mr W M MOLLISON the treasurer, said that during the last two years the expenditure of the Society per member had exceeded the subscription. This was due to one very expensive case which had cost some £7,000. Otherwise the average expenditure over a series of years was well within the subscription limits, and the Society was to be congratulated upon a very sound financial position. Its membership was 15,825, and 1,152 members (616 of them in their first year of registration) were elected during 1937.

On the motion of Dr G F STEBBING seconded by Sir CHARLES GORDON WATSON Sir Cuthbert Wallace was re-elected president. The vice presidents and retiring members of council were also re-elected, Dr Durand's appointment to the secretaryship was confirmed, and votes of thanks were recorded to the solicitors and other officers. The annual report, which was adopted, embodied a narrative by the solicitors to the Society (Messrs Le Brasseur and Oakley) of the more interesting cases arising during the year. It was mentioned that the Road Traffic Act still causes a number of difficulties and that doctors should realize that if the provisions regarding payment of fees for emergency treatment are not strictly adhered to the fees to which they would otherwise be entitled will be irrecoverable. It is particularly to be noted that claims for fees should be rendered to the driver of the vehicle and not to an insurance company or employer.

## THE RED CROSS CONFERENCE

### DELEGATES FROM SIXTY NATIONS IN LONDON

The sixteenth International Red Cross Conference opened at St James's Palace on June 20. It was attended by delegates from nearly sixty countries appointed in most cases both by the Government and by the National Red Cross organization. The British Government delegation was headed by Lieutenant General W. P. MacArthur, Director General Army Medical Services, and the Red Cross delegation by Sir Arthur Stanley and Lord Ebbisham, among other members of the delegation were Sir William Willcox, Sir Harold Lawes, and Dr H. Golden Thompson. The French delegation was headed by M. Basdevant, of the Ministry of Foreign Affairs, and the Marquis de Lillers, president of the Central Committee of the Red Cross in Germany by the Duke of Saxe-Coburg and Gotha (Mr. Aenstools) that of the United States by Mr. Norman Davis, of Norway by M. Colbin, Norwegian Minister in London, the Netherlands by Surgeon General S. W. Prins, of the Army Medical Service, and the Papal State by Sir George Macdonagh. In addition to the Government and Red Cross organizations a number of other bodies sent delegates in an advisory capacity. The League of Nations, the International Labour Office, the International Hospital Association and the Permanent Committee of International Congresses of Military Medicine and Pharmacy were represented. Colonel L. M. Cowell and Mr. A. W. Haskett (Public Relations Officer) attended on behalf of the British Medical Association. Sir Harold Pink and Major R. P. Woodhouse on behalf of the British Hospitals Association. Major General Sir John Duncan on behalf of the Order of the Hospital of St. John and Colonel Donald J. Mackintosh on behalf of St. Andrew's Ambulance Association.

The Conference, which meets every four years, was to have been held in 1935 in Madrid but that being impossible, the venue was changed to London which was last the scene of such an international conference in 1907. After the formal opening and one plenary session at which four commissions (general legal relief and educational) were appointed, the Conference sat in commissions for three days, these meetings being held at the British Medical Association House. It reassembles in plenary sessions on to-day (Friday), when the reports of the commissions will be presented. A report on the general business and conclusions of the Conference will appear in our next issue.

#### Opening Ceremony

At the opening ceremony, over which Sir Arthur Stanley presided, a welcome to the delegates was given by H.R.H. the Duke of Gloucester, Chairman of Council of the British Red Cross Society. He also brought a message from H.M. the Queen, President of the Society, in which she expressed the earnest hope that the Conference would "bring nearer the day when the Red Cross will be universally regarded as an effective guarantee that human sufferings, where they cannot be prevented, shall nowhere continue to go unrelieved."

In the course of his speech the Duke of Gloucester suggested that in the commissions consideration should be given to the question of whether some part at least of the sufferings which are being endured in different parts of the world to-day are not avoidable sufferings which could be prevented by the exercise of that mutual good will which the Red Cross has done so much to engender and the extension of that spirit of chivalry which is fundamental in its work.

The international Red Cross conventions (His Royal Highness continued) and the international co-operation which these conventions guarantee have come to assure to sick and wounded soldiers in war time and to prisoners of war, a degree of protection which as short a time as a century ago might have seemed unattainable. But

simultaneously with the progress made in this direction the evolution of modern methods of warfare has created a new category of war sufferers. I would ask the Conference therefore to consider very carefully whether it cannot usefully make its voice heard on behalf of these unfortunate people. While I fully realize the difficulties in the way, might it not at least be looked upon as a duty incumbent upon the Red Cross to assist with all the moral and material force in its power the protection of women, children and defenceless persons?

#### Responses by Delegates

The first response was made by M. Max Huber, President of the International Red Cross Committee. Nothing can shake the principles which are at the basis of the Red Cross movement, he declared, not because there are no other organizations which join with us in the alleviation of human suffering but because the Red Cross differs in one respect from other humanitarian bodies—it is a thing apart because it came into being on a battlefield and its emblem has become the sign of the protection of those who are defenceless amid the passions which are inevitably aroused by war. The protection accorded by the existing Geneva Conventions to the sick, the wounded, and prisoners of war should be equally applied to all who are equally defenceless. To the consideration of that extension as the Duke of Gloucester had suggested, the Conference would address itself.

Mr. Norman Davis, chairman of the Board of Governors of the League of Red Cross Societies, said that while the Red Cross movement developed through the vision and activity of Henri Duvant, he in turn derived his inspiration from an Englishwoman—Florence Nightingale. It was therefore most appropriate and a source of real satisfaction that at this critical period in world history the Conference should be held in Florence Nightingale's country.

His Royal Highness (Mr. Davis continued) has alluded in feeling terms to some of the great problems which to-day confront the Red Cross, laying particular emphasis upon a possibility which I, for one, should warmly welcome. The questions on the agenda of this Conference provide for various ways and means by which the Red Cross may alleviate distress and suffering whenever called upon to do so. If however we can go further than this and by any action of this Conference help to prevent some of the suffering from arising at all, I may say to your Royal Highness that I am persuaded such action will be taken without hesitation by the Conference and with the cordial support of the Red Cross movement as a whole.

Messages were read from the President of the French Republic, the German Red Cross, the King of Sweden and Prince Tokugawa of Japan, who was described as a most ardent and faithful supporter of the Red Cross.

#### Red Cross Activity throughout the World

At the afternoon session a very long report was read by M. de Rouge, secretary general of the League of Red Cross Societies, reviewing the activities of these societies since the previous conference held at Tokyo in 1934. He mentioned that the German Red Cross had presented to the Conference an outline of the latest developments in its society—that is to say, its adaptation to the ideology of the Third Reich and the complete reorganization of its formations. The Central Committee of the Spanish Red Cross gave a statistical account of the medical activities undertaken, and while this was necessarily incomplete it showed that a great work had been accomplished. After reviewing the reports from many different countries M. de Rouge said that it was impossible to read them incomplete as many of them were without feeling a sincere admiration for the huge task which had been accomplished.

Mr Norman Davis, chairman of the League, said that it was not the function of the Red Cross, nor within its power, to determine the rules and methods of warfare. Nevertheless, it could not be indifferent to the destructiveness of modern warfare and to the appalling increase in human suffering which it entailed. He was glad to note that on the agenda of the Conference was a discussion of a plan for the creation of neutralized hospital areas ('villes sanitaires'). This proposal was referred to the Legal Commission, as was the further question of the function and activity of the Red Cross in time of civil war.

The task of the League of Red Cross Societies, added Mr Davies, grew in importance each year, and the material support of the national societies must likewise increase. The world needed the League, and those national groups which were giving it support were making a genuine contribution to world betterment.

### Red Cross Work in Spain and China

In a long statement on the work of the International Red Cross Committee, M. Max Huber referred to Red Cross enterprise in Spain, the most important action the Red Cross has taken since the great war. Only thirty-six of the national societies out of sixty contributed in money or material to the work of the International Red Cross in the civil war, and 80 per cent of the funds were contributed by four societies only. Only some fourteen national societies responded to the appeal for help in China. In the three centres of international action of the Red Cross during the last two and a half years—Abyssinia, Spain, and China—the national societies have given or collected something under five million Swiss francs (£240,000). The point was made that at the beginning of each conflict contributions rise steeply, but the effort is not sustained after the first year or so.

### THE ST. JOHN AMBULANCE BRIGADE

The report on the work of the St John Ambulance Brigade carried out in 1937 was presented on May 20 to the Chapter General of the Order by Sir John Duncan, Chief Commissioner. In these days of intense activity for everyone it is remarkable that more and more men and women can be found to give up their time and energy voluntarily. During 1937 the Brigade expanded by 151 divisions, representing a personnel of 2,381 over 850 of these new members were boys and girls joining the cadet corps. The total membership of the Brigade has now risen to 84,419, and this is not a climax for the increase has been steady over a number of years and there is no reason to believe that it will not continue. Increased membership has meant increased activity. The number of cases dealt with was 688,823, being over 74,000 more than the year before. Cases included almost everything, from a cut finger to a fatal car smash. The busiest day of the year was Coronation Day, on that day 7,500 men, women, and cadets were on duty and dealt with over 9,500 accidents.

The Brigade has also been busy on the roads. There are 216 roadside huts and 1,148 first aid posts. The presence of these huts and first aid posts contributes to safer roads as they act as a warning to drivers. Staff voluntarily in attendance are able to deal immediately with accidents if they do occur. The motor ambulances also had a busy year. The total mileage was 141,157 and the cars were used for 123,359 cases—11,000 more than in 1936. Apart from their usual work the ambulances were called to 22,300 road accidents and covered 190,000 miles on this work. The St John Ambulance Brigade was to the fore in assisting in air raid precaution arrangements, and the work has already been in hand for three years. These extra activities have added considerably to demands on members' time. It was in fact necessary to set aside thirteen week ends in the year for special instruction. The result of this activity can be summarized as follows:

Instructors trained 6,003  
Members awarded certificates 25,011  
Members of public awarded certificates 10,348  
Four films have been made illustrating A.R.P.

### EPSOM COLLEGE

The eighty-fifth annual general meeting of the Governors of Epsom College was held at the office 49, Bedford Square, W.C., on June 17, 1938, with Dr Henry Robinson in the chair. The President Lord Leverhulme, was unavoidably prevented from attending, as he was in Canada.

The result of the first election of pensioners and foundation scholars was announced by the Chairman, as follows:

#### Foundation Scholarships

Andrew, Alfred T.	Maclean, Robin W.
Beswetherick, Anthony F.	McKintosh, Ian B.
Bisset, Norman G.	Oldershaw, Kenneth L.
Collingwood, Christopher N.	Playfair, Henry R.
Evins, Hugh A.	Robertson, John A.
Huddy, Francis W.	Treves, John K.
Jackson, Markham A.	

#### Pensions

Ordinary and Dr Strong Pensions (£40 per annum)
Goulston, Mrs. Mary J.
Thomas, Mrs. Florence J. M.
Pugh Pension (£30 per annum)
Cooper, Mrs. Annie G.
"Brodie Swell Pension (£30 per annum)
Row, Miss Jane S.
"Highett Pension (£42 per annum)
Eyton Jones, Dr. John A.

In addition, grants were made to various unsuccessful candidates.

The Chairman referred to the loss which the College had sustained by the death of Sir Raymond Crawford, who was for twenty-three years a member of the Council and its chairman for thirteen years. Sir Raymond's administrative ability, wide knowledge of educational matters in general and of medical education in particular, and his personal energy were all placed at the disposal of Epsom College with the one idea that it should take a leading place among the public schools of England.

#### Annual Report and Elections to Council

In presenting the report, Dr Robinson said that over 400 subscribers had signed seven yearly covenants. The report gave interesting details of the progress of the school in work and in play, with some outstanding records attained by Epsom boys and Old Epsomians, and showed that Old Epsomians were among the recent benefactors of the College. For instance, Colonel W. L. Crawford had given £5,000 to found a leaving scholarship and £250 to found a prize for an essay dealing with the Overseas Empire. Mr E. E. Fisher, FRCS, had sent £250 as an expression of gratitude to the College, the sons and daughters of the late Mr William Murray Wilson had established a prize to perpetuate the memory of their father, and Dr W. Rushton-Parker had given £1,000 to be expended for the benefit of science and £100 for the library. Mrs H. G. Tetley had given a further £500 to augment the Tetley Scholarship Fund which she founded a few years ago.

The following members of the Council were re-elected for a further period of three years: Mr D. C. Birtley, Sir John F. H. Broadbent, Bt. M.D., Surgeon Vice Admiral Sir Reginald Bond, K.C.B., Sir Ernest Goodhart, Bt. Mr R. M. Handfield Jones, FRCS, Mr Frederick G. C. Morris, Sir Cosmo Parkinson, K.C.B., Dr Harold Spitta, Mr T. Hollis Walker, K.C., and Dr Daniel O. Twining was elected to fill a vacancy. Dr C. E. Douglas, LL.D. of Fife was elected a Vice President in recognition of his great interest in the College, and the valuable services he had rendered to the Royal Medical Foundation as honorary local secretary for thirty-six years.

The By-laws of the College were varied so as to widen the terms under which contributors can become life governors with a special reference to the widows of subscribers who wish to carry on their late husbands' subscriptions. A new by-law was approved ensuring the solvency of Trust Funds by limiting the value or the number of pensions and scholarships to within the income of the fund.

Colonel Norman C. King, Mr. H. H. Rew and Mr. H. A. Dwyer, F.C.A., were appointed auditors for the coming year and the Chairman proposed a hearty vote of thanks to all honorary local secretaries, the British Medical Association, the Medical Insurance Agency, the Charities Committee of the British Medical Association and the Editors of the *British Medical Journal* and the *Lancet* for all the work that they had done on behalf of the Foundation.

## INTERNATIONAL GUILD OF HOSPITAL LIBRARIANS

The second international conference of the International Guild of Hospital Librarians was held in Bern, from June 7 to 11. Delegates came from Belgium, Finland, France, Germany, Great Britain, Norway and Switzerland and other countries which were not actually represented sent interesting reports about their work together with good wishes for the success of the conference. Very many subjects of hospital library work were discussed and it is evident that steady progress has been made in important directions since the Paris conference in 1936.

Three reports were presented by the British Section of the Guild. Mr. M. E. Roberts (hon. secretary) spoke on "Methods of Establishing Hospital Libraries" and papers were sent by Mrs. Raymond and Mrs. Beddington on "Methods of Collecting Books" and "The Hospital Librarian for Recruitment and Status" respectively. There were some interesting accounts of library work in sanatoria for tuberculous patients and during one discussion it was decided how experiments in Paris have shown that risk of infection is fairly negligible. Great interest was aroused by Dr. Warth's address on "Books and Reading for Mental Patients".

During the conference an important meeting of Swiss delegates was held at which it was strongly recommended that a representative committee should be formed for the purpose of developing hospital libraries in Switzerland and that this should be carried out under the auspices of Veska (the Swiss Hospitals Association) which it was further suggested should be affiliated to the International Guild—a recommendation which added to the undoubted success of the Congress. Dr. Sand, the president of the International Guild at the end of his report announced that an invitation had been received to hold the next conference in London in 1950. The delegates unanimously agreed to this.

All the papers read in English at the conference will be reprinted in numbers of the *Book Trolley*, the organ of the Guild together with summaries of the French and German papers. The latter will be published in full in the journal of Veska which may be obtained from Dr. Otto Binswanger, Kreuzlingen, Switzerland or the hon. secretary, 48 Queens Gardens, W.2.

W. H. Wright and E. B. Cram (*Amer. J. Dis. Child.* Decem. ber 1937) discuss the treatment and control of threadworms. There is no known anthelmintic which in single doses will remove all the worms. In the present investigation tetrachlorethylene seemed to be the best drug for treatment by a single dose, santonin was not as effective as it is usually thought to be. The fact that oxyuriasis is often a familial condition calls for simultaneous treatment of all infested members of the family. Medicated and non-medicated enemas were of value but the prolonged use of these is irksome especially when several members of the same family are affected. Enemas when used too frequently also irritate the large bowel and later cause constipation. Ointments may relieve irritation but do not prevent the migration of the ova from around the anus. Experiments are in progress to find a safe, cheap anthelmintic for this common trouble. It is not usually recognized that the ova of the worms are not deposited in the intestines but are expelled by the gravid female after migration out of the anus on to the perineal region.

## Reports of Societies

### TREATMENT OF CEREBROSPINAL FEVER

A meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health was held in London on May 27 when the subject of discussion was the modern treatment of cerebrospinal fever. Dr. E. H. R. HARRIS was in the chair and the first speaker was Dr. C. G. K. THOMPSON.

Dr. Thompson gave a brief description of the new screw cannula and other apparatus used in the treatment of cerebrospinal meningitis by continuous spinal drainage. The results of this treatment had been encouraging in spite of a 35 per cent case mortality. Large doses of intravenous serum, up to 160 ccm. on three successive days to combat the toxæmia and sterilize the cerebrospinal fluid were administered in addition to the treatment by continuous drainage. He produced the results of an experiment carried out in conjunction with Dr. V. D. Allison of the Ministry of Health to show that (1) serum given intravenously appears in measurable quantity in the cerebrospinal fluid within two hours of administration and that (2) artificial agglutinins also appeared in the cerebrospinal fluid within the same period. This important finding greatly supported the principle of continuous drainage. Twenty-eight cases in all were treated. Nineteen of these were in the severe category in which occurred all the deaths—a total of ten. Six of these were in the main due to the added complication of bronchopneumonia which in the light of past experience could perhaps have been avoided. The actual case mortality from meningitis alone worked out at 1-3 per cent.

### Continuous Spinal Drainage

The drainage was carried out for an average of 150 hours. The greatest amount drained was 4.185 ccm. and the average amount was 2 litres. The treatment showed considerable advantages over the routine diurnal lumbar puncture, the more important of which were the rapid relief of acute symptoms, the avoidance of the blocking of the clefts of the fourth ventricle and the avoidance of loculation of the inflammatory exudate in the subarachnoid spaces—particularly the perineural diverticulae of the cord—which gave rise to the distressing spinal rigidity. It was quite rational to relieve the increased intracranial tension caused in the main by the outpouring of inflammatory exudate from the meninges and the congestive enlargement of the cranio-spinal contents and to keep the pressure normal so that an increased congestion could occur and hasten the process of repair. Any treatment which did not provide an adequate escape for the large amount of meningeal exudate produced entailed a grave risk of distressing sequelae. These sequelae were the result of adhesions round the nerve roots of the cord and brain, set up by loculated exudate.

### Meningococcus Antitoxin and Sulphanilamide

Dr. H. STANLEY BANKS said that everyone would be impressed by the ingenuity of the continuous drainage technique but that his experience had led him to an entirely opposite conclusion as to the treatment of acute cases—namely, that drainage was unnecessary provided that the cerebrospinal fluid could be rapidly freed from organisms. In most cases this could be achieved either by the intensive use of meningococcus antitoxin or by sulphanilamide. In the last four and a half years he had treated 107 acute cases. Thirty-eight had been treated with the serum alone intravenously and spinally with a fatality rate of 16 per cent. Fifty-eight had been treated with the serum intravenously and sulphanilamide in high dosage by mouth, with a fatality rate of 12 per cent, and

eleven selected cases were treated with sulphanilamide alone, with one death. This comprised all the cases observed during the period, except for certain groups of cases which were excluded as not being amenable to specific treatment. In the group receiving combined therapy there were ten infants under 1 year, with one death. An investigation carried out at the Southern Group Laboratory had shown that serum given intravenously in this disease rapidly appeared in fractional amount in the cerebrospinal fluid and was maintained therein for several days. Sulphanilamide given by mouth appeared in the fluid in about the same proportion as in the blood stream, it had to be maintained at a level of about 5 mg per 100 ccm for at least three days. The dosage required in order to secure this was high, averaging 1 gramme per stone of body weight, and in infants two or three times this amount. The dose was reduced after three days and the administration terminated in about nine days. Early cyanosis was not in itself an indication for reducing dosage. It was not due to sulph- or methaemoglobin-æmia. The drug, even in the acute stage of this disease, could be administered by mouth. He considered that sulphanilamide therapy was a most important advance, but that in moderate and severe cases serum should be given in addition in a large dose, not intrathecally but intravenously, or in infants intraperitoneally.

### General Discussion

Dr SAGE SUTHERLAND stated that during the five years 1933 to 1937 201 cases of cerebrospinal fever had been treated in hospital at Manchester. The annual mortality rate varied from 28 per cent to 47 per cent. During the last twelve months the mortality rate, excluding deaths within forty-eight hours was 36.8 per cent, and during this period antibacterial and antitoxic serum was administered intramuscularly, intravenously and intrathecally, the average dosage being about 100 ccm. In a survey of the cases treated during the last five years the lowest mortality rate was 14 per cent, in the 5-10 age group and the highest 67 per cent, in the under 1 year group.

Dr J V ARMSTRONG said that he felt that the principle of continuous drainage—namely, that of giving free drainage to a purulent exudate which was under pressure—was physiologically sound. The method had eliminated basal block, but unfortunately was inapplicable to infants, amongst whom basal block and hydrocephalus were frequent complications. The fact that an infant discharged apparently cured might later develop hydrocephalus should always be taken into account in assessing any form of treatment.

Dr R A O'BRIEN suggested that the favourable results in Dr Banks's series were due to the action of sulphanilamide both on the meningococci and on the streptococci, which might cause fatal bronchopneumonia. Antibacterial serum properly made would protect mice against lethal doses of culture. Miss Branham had recently favoured the use of sulphanilamide as well as of serum proved by mouse experiment to contain protective antibodies.

Dr J E MCCARTNEY said that the most significant point about Dr Banks's work was the swift disappearance of organisms and rapid reduction in the number of cells in the cerebrospinal fluid. The cells indicated the degree of inflammatory reaction and showed that the infection was quickly overcome. In the absence of infection therefore, there were no inflammatory products to remove and repeated puncture and continuous drainage were not necessary. There should be no aftermath of infection due to chronic fibrosis, and hydrocephalus should not supervene. In the continuous drainage method the products of inflammatory reaction were removed but the infection itself was not touched and in consequence chronic inflammation with hydrocephalus was more likely to occur.

Dr ERIC C O JEWESBURY said that there must be general agreement that Dr Banks's results were most impressive. He spoke of six cases at St Bartholomew's Hospital in which sulphanilamide combined with specific therapy and regular

lumbar drainage had been employed. Lack of experience had led to the sulphanilamide being given by various routes and the dosage had been smaller than that Dr Banks advocated. The response had therefore been slower. All the cases however had been severe ones and all had made good recoveries. Dr Jewesbury mentioned one case in which the concentration of sulphanilamide in the cerebrospinal fluid fell after the dose by mouth had been doubled. The concentration and the effectiveness of sulphanilamide in the cerebrospinal fluid seemed to be variable and unrelated to one another. Crawford and Fleming, for instance, found that in one case a concentration of 1.39 mg per 100 ccm in the cerebrospinal fluid sterilized it whereas in another similar case a concentration of 17.8 mg per 100 ccm failed to do so. A constant dose by mouth often led to very variable concentrations in the cerebrospinal fluid.

### ANAEMIA OF PREGNANCY

At a meeting of the Edinburgh Obstetrical Society on March 9, with the President, Professor HENDRY (Glasgow), in the chair, Dr MOIRA STEVENSON read a paper on "Anaemia of Pregnancy."

She said that although most people were aware that anaemia was a common complication of pregnancy and the puerperium, this was not the impression one gained from a summary of the literature. Since the introduction of liver therapy in pernicious anaemia, however, more interest had been taken, and recently many cases of "secondary anaemia of pregnancy" had been recorded, but it would appear that "pernicious anaemia of pregnancy" was very rarely found in temperate zones. It was accepted as common in India, but there the condition was considered to be tropical macrocytic anaemia complicated by pregnancy.

Impressed by the rapid response to liver therapy in some ward cases where "pernicious" anaemia appeared to date from a pregnancy, and by the apparent frequency of puerperal anaemia in the out-patient department, Dr Stevenson began an investigation in 1928. One hundred patients were examined during a period of six years. Some were seen during the routine work of one medical unit of the Glasgow Royal Infirmary, and some as cases of special interest in the Glasgow Royal Maternity Hospital. They were not collected at a clinic for anaemia, and in no way represented the frequency of anaemia in the Maternity Hospital.

For purposes of description she used the simple classification of (1) pernicious, megalocytic or hyperchromic anaemias, (2) secondary, microcytic or hypochromic anaemias. There were thirty cases in the first group, and seventy in the second, but these figures gave no indication of the relative frequency of the two types, as more attention had been paid to the first.

It appeared to be more common than was generally realized. It was a serious and sometimes fatal complication of pregnancy. She detailed her findings and differentiated it from true Addisonian anaemia as follows: (1) It occurred at an earlier age. (2) Multiparity was a predisposing cause. (3) Poor nutrition was common. (4) It was more rapid in development. (5) Achlorhydria was uncommon, but the gastric secretion was abnormal. (6) Retinal haemorrhages were the only signs of involvement of the nervous system. (7) Haemolysis was relatively slight. (8) The blood picture reflected a more plastic marrow, and varied with the chronicity of the illness. The red cells were sometimes deficient in haemoglobin. Price-Jones curves usually showed a broadened base, without a shift to the right. (9) Response to suitable therapy was usually more rapid. (10) Maintenance treatment was not required. With regard to aetiology, it appeared that there was a temporary lack or insufficiency of the intrinsic factor in certain individuals during pregnancy. Dietary deficiency of the extrinsic factor probably played a part in causation.

A brief description of the seventy cases of the secondary group was given. It was more common than the pernicious type though still a rule not so serious. It was a microcytic hypochromic anaemia resembling idiopathic hypochromic anaemia but differing from it in the following features: (1) It usually occurred at an earlier age. (2) While ichthyohydria was common hyperchlorhydria was sometimes found. (3) Icteric tinging of the skin and slight excess of urobilinogen in the urine were common. (4) There was often anisocytosis with considerable numbers of large polychromatic cells. Price-Jones curves showed a broadened base as well as a shift to the left. Leucocytes were sometimes increased. (5) While massive iron therapy usually was the most satisfactory form of treatment the addition of liver was sometimes helpful. (6) Some cases recovered very rapidly and remained well without maintenance iron therapy. The main aetiological features appeared to be the strain of repeated child bearing, dietary deficiency and abnormal gastric secretion with poor absorptive powers.

### General Survey

Dr Stevenson was becoming more and more convinced that these anaemias could not be separated into two watertight compartments. Some resembled pernicious anaemia, and some resembled idiopathic hypochromic anaemia but this was a group which had morphological and possibly aetiological features of both and where the liver factor plus iron were required in treatment.

In the course of the investigation certain questions of interest had arisen the most important being related to haemolysis—slight in the pernicious group and occurring in many cases of the secondary group.

She stressed the importance of adequate nutrition and ante-natal care as possibly preventing their occurrence.

### BRITISH ORTHOPAEDIC ASSOCIATION

The spring meeting of the British Orthopaedic Association was held in London and Oxford on May 27 and 28 under the presidency of Mr NAUGHTON DUNN. The guests included a large contingent of Scandinavian orthopaedists and their ladies, led by Dr GUILDBL (Denmark). Professor WALDENSTROM (Sweden) and Dr PLATO (Norway). One day was spent at the country establishment of the Royal National Orthopaedic Hospital at Stanmore and another at the Wingfield Morris Hospital at Oxford. Clinical demonstrations were given at both hospitals. The material shown covered a very wide range of deformities and disease, tuberculous and non tuberculous. The excellent occupational training centres at both hospitals aroused great interest. During the meeting the following short papers were presented.

*Distribution and Treatment of Extra articular Foci in Tuberculosis Arthritis of the Hip joint*—Mr J. A. CHOLMELEY (London) gave an account of fifty five children treated at Stanmore for tuberculous foci in the immediate neighbourhood of the hip. The most common sites were in the ilium adjoining the acetabulum and in the metaphysis of the femoral neck. In forty three patients the treatment had been conservative and in twelve the focus had been excised. In both these groups the hip joints eventually became involved in the large majority. Less than 10 per cent of the fifty five children escaped with movable hip joints. Thus the conclusion was drawn that attempts to excise extra articular foci had no advantages over conservative treatment.

*Structure and Function in Synovial Joints*—Mr M. A. MACCAILL (Sheffield) elaborated the remarks which he had made in October (Journal 1937 2 1191) on the principles of joint mechanics. He outlined the relation and adaptation of joint function to its lubrication by the synovial fluid and gave a detailed account of the structure and function of

ligaments. He ended by describing several joints in detail in the light of his researches.

*Osteochondritis of the Adult Tarsal Scaphoid*—Mr J. F. BRADFORD (Birmingham) gave details of nine cases of osteochondritis of the scaphoid occurring in adult women and affecting both feet. The characteristic lesion was an oblique splitting of the scaphoid and separation of the two fragments. The smaller outer fragment was displaced dorsally, the larger inner fragment was displaced only gradually and came to lie on the medial aspect of the head of the astragalus. Subsequently gross osteoarthritic changes developed in the mid tarsal joint.

*Operation to Restore Opposition of the Thumb*—Mr F. J. ALLAN (Birmingham) reviewed forty three patients on whom he had operated to restore opposition of the thumb. Marked improvement in the function of the hand had resulted in all but one patient. The operation was applicable to both flaccid and spastic paralyses and involved the insertion of a tibial graft between the index finger and thumb metacarpals so that the thumb was maintained at right angles to the palm.

*Arterial Occlusion in Relation to Volkmann's Contracture*—Mr D. LLOYD GRIFFITHS (Manchester) argued that the venous obstruction theory was no longer tenable as explaining the cause of Volkmann's contracture and that the bulk of the evidence suggested that the condition was due to arterial obstruction. He quoted two patients in whom following occlusion of the femoral artery by a proven embolus changes in every way similar to those associated with elbow and forearm traumas occurred in the calf muscles. A plea was made for a more careful recording of these cases. It was important to record for example whether the radial pulse was present or absent. It seemed likely that the only effective treatment was operation which should include liberal opening of the deep fascia and inspection of the brachial artery. If the artery was obstructed by spasm it was not yet certain what should be done. Periarterial sympathectomy and arterectomy had in the main been disappointing.

*Preliminary Account of a Method of Arthrodesis for Healed Tuberculosis of the Hip*—Mr H. A. BRITAIN (Norwich) illustrated by a film an operation which consisted in performing a short oblique subtrochanteric osteotomy and displacing the distal fragment inwards until its upper end came into contact with the ischium over an area which was sawed with a special osteotome. If the hip was adducted the procedure could be carried out blindly through a limited antero-lateral approach if abducted the classical posterior approach was employed. It was claimed that this ischio femoral arthrodesis was a much sounder mechanical procedure than the usual ilio femoral arthrodesis. In either approach the operation could be performed well away from the diseased joint. Eight patients who had been observed for at least two years since operation were reported in all but one who committed suicide after the removal of the plaster. The functional results were excellent and there had been no recurrence of the disease.

The association dinner was held at the Langham Hotel and the after dinner speeches were reported in the *Journal* of June 4 (p. 1227). Other extremely enjoyable features of the social programme were visits to Windsor Castle and Hampton Court tea in St John's College Oxford a sherry party at Blenheim Palace by invitation of the Duchess of Marlborough, and a dinner in New College Oxford at which Viscount Nuffield was present and addressed the association.

The University Grants Committee has now published the returns for the academic year 1936-7 from universities and university colleges in receipt of Treasury grant (H.M. Stationery Office 1s 3d). The number of full time students to which this relates was 49,689 of whom 36,612 were in English, 3,197 in Welsh and 9,880 in Scottish university institutions. Of the total number 13,263 are grouped in the section headed Medicine and Dentistry—11,430 men and 1,833 women.

## Local News

### ENGLAND AND WALES

#### Medical Aid in Childbirth

The Minister of Health has communicated with local supervising authorities (Circular 1705) on the methods they might suitably adopt in order to secure that the best obstetric skill is available to expectant mothers on occasions when midwives have to call in a doctor. The suggestions made follow consultation with the various local government bodies interested, as well as the British Medical Association. The recommendations are

(1) That a panel of doctors who will be available for this service should be drawn up for the area of each local supervising authority

(2) That a small advisory committee of general practitioners and obstetric specialists should be set up in each area under the chairmanship of the medical officer of health to advise the authority in regard to the operation of the arrangements and on any alterations which may be found necessary in order to secure and maintain a high standard of obstetric practice

Such arrangements are facilitated by the fact that under the Midwives Act of 1936 midwives attending patients in their own homes are in the main, and increasingly, the employees of the local authority. They will be supplied with a copy of the list of doctors and will ask their patients, at an early stage, to select a doctor, to be sent for in case of need, from the panel. It is hoped that the adoption of arrangements on these lines by local authorities will help in reducing the maternal mortality rate still further

#### Ready Reference to L C C Hospitals

For the two pence which the Good Samaritan tendered to the innkeeper his successor in modern London may provide himself with a booklet issued by the London County Council giving every necessary particular of its general and special hospital services and ambulance service so that the sick and injured may be sent to their appropriate destination with the minimum of delay. The orange-covered booklet takes up next to no room in the doctor's pocket or on his desk, and it contains just those details the busy and harassed practitioner wants to have at hand—not a laudation of the largest municipal hospital service in the world, with facts and figures which are merely interesting, but such things as essential telephone numbers, the exact whereabouts of the different hospitals and clinics, the bed accommodation, the name of the medical superintendent, the availability of ambulances, the charges for out-patient treatment, the hours during which clinics are open, the fees for the attendance of midwives, and so forth. The Council administers thirty-seven general hospitals and a rather smaller number of special hospitals, but many of the general hospitals are themselves special in the sense that they provide particular services not common to them all. For example, the treatment of cancer by means of high-voltage x-ray apparatus and radium is available at Lambeth and Hammersmith Hospitals, certain special and expensive technical appliances such as the electrocardiograph are at present located only at certain hospitals. Eight hospitals have psychiatric out-patient clinics. Even the infectious diseases hospitals are differentiated. Thus at various hospitals there are units for puerperal fever cases, for diphtheria carriers, and for acute poliomyelitis. Maternity units are provided at twenty-two general hospitals. It is mentioned that extensive arrangements are made to co-operate with the metropolitan borough councils, which are respon-

sible under the Public Health (London) Act for maternity and child welfare. Whether the expectant mother elects to attend an L C C clinic or a borough clinic the reciprocal arrangements obtain so that she receives the expert supervision necessary during pregnancy.

#### The British Association Meeting

This year the annual meeting of the British Association for the Advancement of Science will be held at Cambridge from August 17 to 24 under the presidency of Lord Rayleigh. There will be twelve sections, the president of the Section of Anthropology is Professor Gordon Childe, of Psychology, Dr R. H. Thouless, of Botany, Professor W. Stiles, and of Chemistry, Professor C. S. Gibson, OBE. The preliminary programme has been issued and may be obtained from the office of the British Association, Burlington House, London, W1. Among the subjects to be dealt with by the presidents of sections and in discussions are the chemistry of gold, problems of the Australian aborigine, repercussions of synthetic organic chemistry on biology and medicine, the effect of the cinema and wireless on the life of the school child, magnetic alloys and x-ray methods, the eye and brain as factors in visual perception, problems of road and air transport, and scientific investigation in relation to the community generally. Various receptions and entertainments are being organized by the Senate of the University and by Colleges. Owing to the coincidence of the International Physiological Congress, which this year is to be held at Zurich from August 14 to 19, the Section of Physiology will not hold separate meetings at Cambridge. The annual meeting of the British Association in 1939 will be held in Dundee.

#### King Edward VII Sanatorium, Midhurst

The report of King Edward VII Sanatorium, Midhurst, for the year July, 1936, to June, 1937, shows that 262 patients were admitted during the twelve months, of whom fifty-seven had previously been in the institution. The number of patients discharged, excluding nineteen who remained less than nine weeks and thirty-eight who were readmitted, was 189. Of these no fewer than 154 were classified on admission in group I or II, which according to the classification used at Midhurst, means that in none did the disease, if of "slight severity," affect more than the whole of one lobe, or, if "severe," more than half of one lobe. The degree of severity is based on physical signs by "disease of slight severity" is understood "disseminated foci characterized by slight dullness, indefinite rough or weak vesicular or bronchovesicular breathing, and fine medium crepitations," by "severe disease" is understood "massive infiltration recognized by definite dullness, broncho-vesicular or bronchial breathing, with or without crepitations." This classification, although admittedly unsatisfactory, does show that a high proportion of the patients admitted at Midhurst are relatively early cases. The average duration of disease was one year eleven months, but as the extreme limits were four weeks and twenty years the average figure really gives no useful information. Of the 154 patients in groups I and II ninety-one were discharged as "arrested" (corresponding to "quiescent" in the Ministry of Health classification). Of the twenty-seven patients in group III one only was discharged as "arrested", in the remaining eight discharged patients no evidence of pulmonary tuberculosis was found. Sixty-two of the 189 patients still had positive sputum on discharge, and the medical superintendent suggests some factors that account for this. The most important appears to be the short average length of stay—just under six months—and the reason given for this is pressure on the available beds in the sanatorium. If this explanation is correct (almost all authorities are agreed that six months in an institution is quite inadequate for the satisfactory treatment of the majority of cases of phthisis) the question of the accom-

meditation at this sanatorium deserves the earnest attention of the council of management and the sympathy of the public, since the Midhurst Sanatorium is one of the very few institutions in this country that cater for tuberculous patients of the middle class.

#### Seaside Convalescent Home for Women

The new convalescent home for women which the London County Council has provided at Margate was open for inspection last week. The site of the home was previously occupied by Princess Mary's Hospital for Children, a hospital transferred to the Council from the Metropolitan Asylums Board under the Local Government Act 1929 and formerly used for the treatment of children suffering from surgical tuberculosis. In February 1935 however the Council decided to transfer children suffering from this disease to its Heather Wood Hospital at Ascot Berkshire. In the following June it decided to reconstruct Princess Mary's Hospital in order to make it suitable for the reception of convalescent women. The patients will be sent to the home on the recommendation of the medical superintendents of the Council's London hospitals, and while at Princess Mary's Convalescent Home their treatment will be continued and completed in ideal surroundings. The home is equipped to give massage and electrical treatment. It stands in about four acres of ground and has accommodation for 223 women and fourteen babies. The first batch of patients was admitted on June 10. The work of reconstruction which has cost over £76,000, has involved the remodelling of some of the existing buildings and the erection of a new dormitory block on a site previously occupied by four single story blocks. Everything possible has been done for the comfort of the women during their stay. Great improvements have also been made to the grounds of the home. New gardens have been made and the existing gardens remodelled.

#### Joint Tuberculosis Council

A meeting of the Joint Tuberculosis Council was held in London on May 21 with Dr S Vera Pearson in the chair. Dr N Lloyd Rusby and Dr R L Midgley were welcomed as new members representing the Tuberculosis Association and the Tuberculosis Group of the Society of Medical Officers of Health respectively. Information concerning a proposed visit to this country of French tuberculosis physicians was discussed briefly and the Council agreed to co-operate in every way with arrangements which the National Association and the Tuberculosis Association might make for the visitors. The resignation of Dr F G C Blackmore from the Council was accepted with regret and the secretary was instructed to convey to Dr Blackmore the thanks of the Council for his work. Dr W Brand who has done so much for postgraduate study in this country was elected a co-opted member of the Council. No additional committees were set up, but it was decided that the Artificial Pneumothorax (Dr Trail convener), Employment (Dr J B McDougall convener), Radiology (Dr G Jessel convener), Nursing (Dr Carling convener) and the Finance and Publicity Committees should remain in office. The committee dealing with work in the Colonies is now to become the Overseas Committee, with Dr F Heat as convener. By the requisite two-thirds majority two alterations were made in the constitution which will allow of wider representation on the Council. An important discussion was initiated by Dr G Lissant Cox who moved that the Ministry of Health be asked to resume publication of the summary of returns of work rendered to the Ministry under Memorandum 37/T. He did not suggest that they should necessarily be published monthly but they should be available at two- or three-monthly intervals. Support for the motion was given by Drs Jessel, Tattersall and Sutherland and the Chairman pointed out that one of the great advantages in the

returns was that they tended to stimulate the more backward local authorities. It was resolved that a deputation comprising Drs Lissant Cox (Lancashire), Sutherland (Manchester), Tattersall (Leeds) and Professor Jameson (London) should meet the Ministry to discuss the matter more fully and report back.

#### Harveian Society Banquet

The Curators of Patronage of the University of Edinburgh of London was held at the Merchant Taylors Hall on June 14 with the President of the Society, Sir Alfred Webb Johnson, in the chair. "The Society" was proposed by Major the Hon J J Astor MP. Major Astor sketched briefly the life of William Harvey and referred particularly to Harvey's dissection of the toad believed to be the familiar of a witch at Newmarket and to the part that Harvey played in the trial of the Lancashire witches. He said that one of the most striking things about Harvey was the fact that he had been demonstrating the circulation of the blood for nearly twelve years before rushing into print. This seemed to suggest a lack of news sense to those who were accustomed to seeing important medical discoveries announced in glowing though perhaps premature terms to day. In replying Sir Alfred Webb-Johnson referred to the generosity of Sir Buckton Brown and in connexion with Sir Arthur Hurst's Harveian lecture recounted the tale of an ostrich that swallowed the book of common prayer and was able to digest everything except the Thirty-nine Articles. The Society hoped some day to have a home of its own where all the Harveian relics that it possessed might be placed. He pointed out that the annual prize of £100 would be given this year for the best essay on the value of periodic medical examinations in the prevention of serious disease. Dr John Taylor then proposed The Visitors a toast to which Captain H F C Crookshank MP, the Rev Patrick McCormick and the Hon Mr Justice Humphreys responded on behalf of the many distinguished guests.

## SCOTLAND

#### Edinburgh Chair of Medicine

The Curators of Patronage of the University of Edinburgh on June 14 appointed Professor L S P Davidson to the chair of medicine in the University in succession to Professor W T Ritchie who retires at the end of the present session. Professor Davidson, who at present holds the post of regius professor of medicine in the University of Aberdeen began a medical course at Edinburgh in 1911. This was interrupted by the war during which he served for three years as a captain in the Gordon Highlanders but when he was invalided out of the Army he resumed his medical studies graduating M B Ch B with first class honours in 1919. In 1925 he secured his M D with a thesis for which he was awarded a gold medal and in the same year was elected a Fellow of the Royal College of Physicians of Edinburgh. After various resident appointments he became assistant to the professor of bacteriology in Edinburgh and later assistant to the professor of medicine. He was subsequently appointed an assistant physician to the Royal Infirmary of Edinburgh. During this time he did research work under a grant from the Medical Research Council, and published a number of papers. It was in 1930 that he was appointed professor of medicine in the University of Aberdeen succeeding Sir Ashlev Mackintosh. In the Aberdeen appointment he has been a popular and successful teacher who has gained a reputation for energy and scientific enthusiasm. It is understood that at Edinburgh Professor Davidson will act both as a physician to the Royal Infirmary and as director of the Medical Unit in the Western General Municipal Hospital.

## University of Aberdeen

At a meeting of Aberdeen University Court on June 14 the resignations of Professor L S P Davidson from the chair of medicine and of Emeritus Professor R W Reid from the post of honorary curator of the Anthropological Museum of the University were accepted. A gift of £5,000 from Imperial Chemical Industries, to be applied towards the cost of erecting a new chemistry department at the University was intimated. The Court agreed to a general reconditioning of the buildings at Marischal College, at an estimated cost of £144,000, to provide up-to-date accommodation for the departments of physiology and anatomy with additional accommodation for several other departments, and for new examination halls and administrative buildings. This work is to be carried out at Marischal College when the clinical part of the medical school has been removed to the new buildings, which are almost completed at Forresterhill in connexion with the new Royal Infirmary and Joint Hospitals Scheme. It is expected that these new medical buildings will be ready for formal opening in September. Plans were also approved for a new residence near the buildings of the Joint Hospitals Scheme to house final-year medical students in order to facilitate clinical training during the final year.

## Proposed Maternity Centre for Moray, Nairn, and Banff

At a meeting of the Public Health Committee of Moray and Nairn Joint County Council, held at Elgin on June 6, a letter was read from the Department of Health in regard to the question of a joint maternity hospital for Moray, Nairn, and Banff. The question arose out of a proposal by the County Council of Banff to erect a small maternity annex to the Seafield Cottage Hospital at Buckie. The Department referred to the recommendation in the report on maternal mortality in Scotland, issued in 1935, which pointed out that the provision of small units did not secure the high standard of service and of specialist skill that were essential for maternity cases if the death and disability rates were to be sensibly reduced. The Department further expressed the view that centralization of institutional treatment for maternity cases must be carried out when it was at all possible, and that the situation of a hospital was not of so much importance as the adequacy of the treatment available. The problem in this case might be solved by the provision of an institution for, say, twenty-five beds by the combined local authorities of Moray, Nairn, and Banff. The chairman of the meeting stated that the present practice in these counties was to use Aberdeen, but this city was rather far away, and it would be of advantage to have a maternity hospital and specialist nearer at hand. The medical officer of health for the joint county had originally proposed to combine with Inverness, where, however, there was as yet no maternity accommodation, and now proposed that an attempt should be made to secure co-operation with Banffshire. It was agreed that the matter should be further investigated.

## Astley-Ainslie Institution

The annual report of the Astley-Ainslie Institution, Edinburgh, shows that there have been several innovations during the year. A school conducted for the children undergoing treatment has been recognized as a hospital school under the Education (Scotland) Act, 1918. A training centre has been opened for occupational therapy in the institution, and a detailed scheme comprising a two and a half years course of instruction has been inaugurated, five students being enrolled for the first term last October. A scheme of shorter hours of duty for nurses has been introduced, their working hours have been reduced to an average of ninety-six a fortnight. The total number of patients treated during the year was 1186 and it has been noted that men tended to pass through the hospital rather more quickly than women.

## Correspondence

Telephoned Prescriptions for Poisons  
A Warning

SIR—A number of instances of non compliance with an important provision of the Poisons Rules has been brought to the notice of the Pharmaceutical Society by the inspectors under the Pharmacy Acts, and the Society, after consultation with the British Medical Association, finds it necessary to warn both practitioners and chemists that further breaches of the Rule may be followed by prosecutions.

The Rule referred to provides that the poisons listed in Schedule 4 of the Poisons Rules may be supplied to the public only on medical prescription. Those in common use are einchophen, amidopyrine, and the numerous barbiturates. They may be supplied direct to medical practitioners in response to a telephone order, but not to patients on a telephoned prescription. Reports from the Society's inspectors show that many practitioners are ordering and chemists are supplying these drugs to the public by means of telephoned orders.

In these circumstances the Society, as the authority responsible for the administration of the Rule, can no longer acquiesce in non compliance with its provisions and must shortly bring offenders before the courts. The Society is most reluctant to proceed to extreme measures and before doing so, wishes to make this appeal to medical practitioners to observe the legal obligations placed upon them. A similar appeal is being made to chemists.

Medical men will perhaps realize that the pharmacist is placed in a difficult position. To comply with the regulations it is his duty to refuse to supply these drugs on telephoned prescriptions, but he is naturally unwilling to offend a practitioner in his neighbourhood. The abolition of "telephoned prescriptions," though causing inconvenience, need not affect adversely the relationship between doctor and pharmacist, and I have little doubt that medical practitioners will appreciate the necessity for strict compliance with their legal obligations—I am, etc.,

HUGH N LINSTED,

Secretary, Pharmaceutical Society  
of Great Britain

London, W C 1, June 17

## Matrimonial Causes Act

SIR—The medical man immediately concerned with the Matrimonial Causes Act is the patient's regular attendant—either the medical superintendent or medical officer of the hospital in which the patient resides. He is confronted by a twofold problem when called upon by the prospective petitioner to assist in operating the Act. First, he has to satisfy himself whether the patient in question is incurable, and, secondly, he has to decide whether to pass his opinion on to the petitioner. It would be doing less than justice to medical officers in mental hospitals if the situation in which the Act places him were interpreted in a legalistic light, and this is what contributors to the discussion have been inclined to do. The medical officer is not nearly so much concerned with the possibility of being involved in litigation in consequence of his participation in the divorce proceedings—though such concern may arise later—as with the ethics of giving

an opinion which may have disastrous results for his patient.

There is nothing really in dispute about the patient. The patient has been in the mental hospital for five years or more, and no one will question that he or she is insane. As for the prospects of recovery, figures show that five years' residence in a mental hospital indicates such a degree of chronicity that they become practically nil. What agitates the medical officer is not that he should be asked to take part in a battle of opinions—for there is really no foundation for any considerable divergence of opinion—but that his voice must necessarily condemn his patient to isolation. The patient matters to him above all else. In participating in the divorce proceedings he puts himself against the patient by the very nature of the unfavourable prognosis he must express. To focus his distress on the breach of professional secrecy which is involved or on the possibility of vindictive litigation which may follow in error of judgment on his part gives an entirely false rendering of his feelings and distorts the problems the Act create. It is his care for his patient and not for himself that produces the dilemma. How is the medical officer to be released from his predicament for the law must be fulfilled? The only way it seems to me is for the court to appoint experts to assist it, not for their expertness but it noted but because they have no professional relationship to the patient. In this way the medical officer would be absolved from a duty under the Act which would do violence to the feelings of protection which he entertains for his patient.

The question of incurability is by no means so formidable as is generally supposed. A review of 3700 cases resident over a period of seventeen years in a county mental hospital yielded a recovery rate of not more than 0.4 per cent after five years' residence, this works out to about 0.7 per cent of the total cases left in hospital after five years. Within the limits of this probability of error a medical man can express himself with confidence on the question of incurability. If he were to attempt to reduce the margin of probable error by relying on the symptoms of the case he might very well produce a greater degree of error—I am etc.

### Tuberculin in Diagnosis

SIR—The replies which you have published to my letter (*Journal* May 21, p. 1131) concerning the evidence for the value of the tuberculin reaction in the diagnosis of active tuberculosis have not entirely cleared my mind of doubt. It was with the diagnostic application only that my letter was concerned. Dr Camiac Wilkinson's reply (June 4, p. 1234) if I understand it correctly seems to deal mainly (or is it solely?) with the therapeutic application. I have been unable to scrutinize the results of his investigations which he mentions as being incorporated in his book *Tuberculin in the Diagnosis and Treatment of Tuberculosis* as I have not yet been able to obtain a copy of the book.

Dr Halliday Sutherland says (June 4, p. 1233) that I do not appreciate the difference between generic and selective tuberculin reactions. I am well aware that such a distinction is made by some but as yet I have not seen proof of its validity. Dr Sutherland states his belief but offers no evidence to support it. The quotation from Bandler and Roepke as he gives it makes no distinction whatever between generic and selective reactions. And Kolmer's work in cattle is not relevant to man as

I understand that the results of tuberculin injection in these animals are not comparable with those obtained in man. Since the tuberculin reaction [in man] does not tell us the difference between latent infection and active disease the tuberculin reaction cannot be used as a diagnostic agent in tuberculosis. In cattle however a positive reaction usually means active disease (Simplic in *Agents of Disease and Host Resistance* by Gay and associates 1935).

I am relieved to find that I had misinterpreted Dr John R. Gillespie's description of his method for diagnosing active tuberculosis by the tuberculin reaction. I had not written for his paper because I understood from his first letter that it dealt only with the technique of administering tuberculin in diagnosis and treatment and not with the evidence for its diagnostic value. I have since read it and it seems to me that this is indeed the case. I have been unable to find in it any of the evidence I sought.

Dr H. S. Burnell Jones (June 4, p. 1234) seems to me to assess the position well when he says: "It is impossible for those who believe that the earliest diagnosis of pulmonary disease can be made with tuberculin to bring forward convincing evidence that such diagnosis is reliable. It would seem therefore that like many things in medicine the value of tuberculin as a diagnostic agent rests upon belief rather than upon scientific proof—I am etc."

J. R. FORBES

### Anti-venereal Measures

SIR—In your editorial note in the *Journal* of June 11 (p. 1277) on anti-venereal measures in Scandinavia, you appear to accept the conclusions of the Commission that almost equally good results in reducing the incidence of syphilis have been obtained in those countries where there is no compulsion to undergo treatment. In arriving at these conclusions the Commission were content to compare the present day incidence of the disease in Britain and the Scandinavian countries omitting—one would like to think by accident and not by design—the far more relevant comparison of the actual reduction in the number of cases that has occurred in these countries in the post-war years. According to the Commission's report (p. 67) the number of cases of syphilis occurring in Sweden in 1935 totalled less than one-thirteenth of the figure for 1919, in Stockholm it was less than one twentieth. Not even the most ardent supporters of our English come and go-as you please methods of dealing with venereal disease will dare to claim anything comparable for England or London.

According to the Ministry of Health's official figures the number of cases of syphilis fell from 25,000 in 1922 to 18,000 in 1936—a reduction of less than 30 per cent. In Denmark during the same period the figure fell from 2,400 to less than 800—a reduction of over 300 per cent. Yet the Commission (p. 120 of their report) claim that in the countries employing compulsory treatment and in those which rely on a voluntary system the degree of success in reducing the incidence of syphilis has been broadly similar and that therefore compulsory treatment has not been an important factor in influencing results. While one has every respect for the clinical acumen of the personnel of the Commission one may be forgiven for questioning the accuracy of conclusions based on the assumption that 30 and 300 per cent are even broadly similar—I am etc.,

Brentwood, June 14

ROBERT FORGUS

## The Changing Ground of Surgery

SIR—I read with interest Mr W H Ogilvie's address in the *Journal* of June 4 (p 1193), and feel that some discussion on certain points would be of value.

Mr Ogilvie states that duodenal ulcer is essentially a disease of civilization. I think observers in the Tropics, working among mainly uncivilized natives, should try to check up on this. In Uganda my observations, in at least three regions, suggest that peptic ulcer is far from uncommon, and all varieties can be diagnosed or suspected, clinically in the absence of special methods—such as x rays—which do not happen to be available. Some time ago I was particularly interested in the frequency of the occurrence of pain in the chest which the natives always believed to be due to old syphilis. I very soon came to regard this symptom as due to trouble in the stomach and duodenum and with patience and avoidance of leading questions a fairly typical history was often elicited and epigastric tenderness was often present with a tendency to propagation upwards to a point about half-way up the sternum. On clinical grounds it frequently appeared that there was trouble in the duodenum or in the pyloric region and there was generally a marked relation to the taking of food. It so happened that I was to receive confirmation of the view taken—for example that peptic ulcer was fairly common—because Mr A H Mowat, surgical specialist, joined us in 1931, and I think I am correct in stating that he was only a few months in the Protectorate when he was proving by laparotomy the existence of duodenal ulcers.

It is surprising how often one meets with cases of this kind among the most primitive peoples—natives with a history going back for years, and with a facies which can be noticed yards away. I recollect, some years ago, performing a necropsy on a native who came in dying as the result of a large haemorrhage from the bowel. There was a duodenal ulcer, which had caused a large excavation in the head of the pancreas. This had opened the artery and the haemorrhage had been entirely within the gut. The interest of the above lies in the fact that the native is almost entirely a vegetarian, and the food eaten contains only a small proportion of protein. As Hurst stated about 10 per cent of individuals have a hypersthenic gastric diathesis, this is obviously true of the native also, and it is certain that the protein-deficient diet does not check excessive secretion of HCl. Must we look for other factors than the hypersthenic diathesis to explain the causation? Worry and overwork are negligible among natives, who are often non-smokers.

Mr Ogilvie suggests that appendicitis may have a dietetic cause. I have stated that our natives are mainly vegetarian. I can definitely support Mr Ogilvie by stating that in the last ten years I have only found three cases in Uganda. One was chronic, and the diet was probably vegetarian. One was a perforation with general peritonitis; the diet was more mixed. The third was a localized abscess, the dietary included meat.

It may be worth while here to state that malignant disease appears to me to be as common in Uganda as at home. I have seen most types, and sarcomata and epitheliomata figure quite largely, certainly in my own practice. The belief that malignant disease is uncommon among primitive races appears to have originated before the disease was looked for—I am, etc.,

JUNE 16

## Cancer and Vitamin A Deficiency

SIR—Dr J L Mott in a letter in the *Journal* of February 19 (p 421) suggests that the high maternal, tuberculosis and gastric cancer mortalities in North Wales might perhaps be due to a low amount of vitamin A in the diets of the people of this area. It might perhaps be helpful to estimate the daily intake of vitamin A of those races among which cancer is very rare. Sir Robert McCarrison has told us that he did not see any cases of cancer during the seven years that he spent with the people of Hunza. The great consumption of apricots and the high vitamin A content of some of the Indian green vegetables suggest that the diet of these people may be high in vitamin A. Dr Ernest H Tipper in *The Cradle of the World and Cancer* states that among the two million people of the Bene tribe living in the palm belt of the Niger he saw no cases of cancer in twenty years work there; he also informs us that these people use 4 oz of red palm oil daily. The *Indian Health Bulletin* gives the vitamin A content of this oil as 44,000 international units per 100 grammes, which represents the rather amazing figure of approximately 50,000 units of vitamin A from this one food daily. Compare this with the daily intake of the people of the United Kingdom given in Sir John Boyd Orr's *Food Health and Income* of 774 international units in the poorest group and 2,875 units in the wealthiest group.

Whether necropsies on children of the Bene tribe would show that 63 per cent of them suffered from infections of the ears or sinuses, as shown by Dr J H Ebbs to be true of the children examined in Birmingham, is a question of considerable interest. It is not unreasonable to suggest that a daily intake of vitamin A of between 775 and 50,000 international units may impart immunity to such infections. If we could know the vitamin, mineral, protein, etc., content of the daily diets of the world's healthiest races we might be able to arrive at a truer estimate of the optimum quantities of these food essentials. If any such investigations have been made I should like to know of them—I am, etc.,

Auckland May 9

V E HASTINGS

## Tonsillectomy

SIR—Referring to Mr Lionel Collidge's interesting contribution on tonsillectomy (*Journal* June 11, p 1274) I would like to point out that he, in common with most others, continues to repeat an error with regard to the so-called capsule. Sound surgery must be based upon correct anatomy, and the tonsil problem will never be solved until this fact is recognized. Mr Collidge says the tonsil is not in direct relation to the superior constrictor muscle but is separated from it by the pharyngopharyngeus. The point I wish to make is this: the so-called capsule is not the capsule at all but either aponeurosis—as Mr Collidge says—or the constrictor, and that as such every effort should be made to leave it behind. I have endeavoured to solve the problem by modifying the guillotine so as to employ it as a clutch, into which I draw the tonsil with forceps. A further device secures a single ligature which when released surrounds the base of the tonsil so that all is safe in a single pedicle. This is severed by means of a controlled narrow blade attached to the instrument and operating not on the slot principle but rather on that of the bacon

ster Cases so operated upon have been very satisfactory there being no raw surface and no bleeding.

I should have added before this that the true anatomical capsule is a band of fibrous tissue which holds the renal substance together—quite a different structure from that generally understood and described. Professor M. R. Drennan anatomist of the Cape University South Africa made many sections for me to prove this point and he suggests that those interested should turn to the first edition of Lewis and Stohr's *Textbook of Histology* which is edited by Bremer—I am etc.

London June 14

J. L. AYMAR

### 'The Psychology of the Medical Profession'

SIR—I would suggest to Dr. A. J. Brock and to others who are of his mind, that they should authorize their housemaids to destroy all medical circulars as they arrive. This will then be preserved from the influence of insidious propaganda against which apparently five or six years of medical education have afforded no protection. Secondly I would suggest to your correspondent that he should seriously consider whether he or any of his colleagues is in a strong enough position to adopt a patronizing attitude to the literature and products of these commercial organizations.

My own experiences since qualification—embracing periods as H.P. in a London hospital casualty officer in a country hospital medical officer in a mental hospital clinical assistant to a neurological hospital ship surgeon lecture tenens in varying types of practices and in my own practice—have forced me to the by no means unique conclusion that the majority of prescriptions issued can have no possible desirable therapeutic effect. In fact many of these prescriptions are not even given with the intention that they should exert any well defined pharmacological action but merely to make the patient feel he is getting some benefit. Of course the patient who is given a tonic with a little strychnine a little quinine and a lot of water receives also a lot of suggestion. This suggestion which might with equal truth be called "barney" has as its implicit basis the inculcation of faith in the mixture and hence recovery through faith. How then can organized medicine honestly condemn the worst of the proprietary remedies which are advertised to the medical profession? Remedies advertised to the general public are in a different category, as they introduce the potentially harmful element of self medication.

There are of course many valuable official drugs but the need to use these arises relatively seldom in the course of an average general practice. Furthermore many practitioners are unwilling to reflect on the probable pharmacological actions of the medicines which they prescribe so freely or to use them intelligently. Instead they are content to order perhaps a dozen stock mixtures in Winchester bottles—for example mist gastric co conc mist gastric co conc pro infant mist hepat et diuret co conc. In a country practice at which I had the misfortune to act as locum the favourite prescription for any functional nervous disorder was 5 drops of tinct iodi made up to 8 oz with tap water! In this case the doctor did his own panel dispensing and economy was a material consideration.

These examples are not exceptional. They constitute the stuff of which medical practice is made. Squeeze the clamp on the rubber tube of the Winchester quart allow one ounce of the coloured fluid to run into the 8 oz bottle, fill up at the tap, and—hey presto!—a mistura is

made! Not a patent medicine but *real* medicine from the doctor. In the wealthier type of practice the proprietary remedy often replaces the stock mixture of official drugs and a physical examination (often omitted in a mist gastric co conc practice) is thrown in. Many of these proprietary remedies are useless and are advertised by means of specious claims but their utility is no less than that of the tonics or cough mixtures prescribed or dispensed from official drugs. They cost more but they are more elegantly dispensed and more attractive to the patient. Many practitioners are as credulous as their patients in attributing healing powers to their pills and mixtures and keep little notebooks of favourite prescriptions which in most cases were oracularly disclosed by a long since deceased physician at a teaching hospital.

During the last decade or so the expenditure of vast sums of money and the indefatigable labours of first-rate chemists pharmacologists and biologists employed by modern chemical and dye industries promise to change the face of medicine. Active principles of drugs are isolated and their actions recorded with precision. Vitamins and hormones are synthesized in the laboratory and made available in bulk. New and hitherto unknown substances with powerful and well defined therapeutic actions are discovered. Nearly every major advance in the realm of drugs or therapeutic substances has resulted from the collaboration or original work of industrial chemical firms. For every new substance which has finally been placed in the hands of the medical profession there are hundreds which have been tried and discarded. Were all the remedies introduced by commercial organizations to be withdrawn the structure of modern medicine would collapse.

With regard to the question of medical circulars, pamphlets and booklets I would suggest that the lack of knowledge of many practitioners with regard to the recent developments in biochemistry—for example the sex hormones—is little short of astounding. For those who have no time to read the medical journals the circulars from the scientific commercial firms and the visits of representatives often constitute a necessary reminder of advances in therapeutics.

Though the argument in this letter may seem to be overstated it may perhaps serve as an antidote to the complacent and unthinking denunciations of the pharmaceutical industry by members of a profession which is itself far from invulnerable. It is not for nothing that Parliament has recently voted a sum of £30,000 for the foundation of an institute for chemotherapeutic research in Great Britain which is to be conducted on the systematic lines of the research laboratories of German and Swiss chemical firms—I am etc.

June 9

N. HOWARD JONES

### Tetanus and Ectopic Pregnancy

SIR—In the *Journal* of April 9 (p. 779) I read the interesting report from Mr. Frank Stabler of a case of extra uterine gestation with a live child. Although these cases are comparatively rare it is perhaps worth pointing out the possible risk of tetanus supervening if the usually accepted modern treatment of leaving the placenta and membranes in the abdomen to absorb is adopted. Even in the presence of strict asepsis there is some evidence that tetanus infection may be transmitted from the bowel to the adherent and absorbing placenta. A case of my

own which had this tragic termination is recorded, along with a successful case of Dr Eula Enos, in a paper published in the *Chinese Medical Journal* for January, 1937. A preliminary dose of anti-tetanus serum is such a comparatively easy precaution to take that I feel it is worth while to draw attention to this point—I am, etc.,

Lester Chinese Hospital,  
Shanghai May 21

AGNES E TOWERS

### Acriflavine Emulsion

SIR—In his letter in the *Journal* of March 26 (p 697) on acriflavine emulsion, Professor L P Garrod asks that the assertion I made (January 29, p 256) that a 1 in 1000 emulsion of acriflavine in equal parts of lime water and olive oil is 'highly antiseptic' should be supported by proof additional to that afforded by clinical experience alone. Through the courtesy of Major-General Marrian Perry, Director and Professor of Pathology at the R A M C College Millbank, London, I have had an experiment carried out on the antiseptic activity of this emulsion, and quote his report below.

Acriflavine emulsion was prepared according to the formula suggested by Dr J Walker Tomb

Acriflavine (B P)	1 gm
Lime water (B P)	500 ml
Olive oil (B P)	500 ml

In the course of a week only slight separation of the components of the emulsion took place

May 10 1938

Two tubes of broth were sown with <i>Staph aureus</i>
Two " " " " <i>B. pyocyanus</i>
Two " " " " <i>B. coli</i>

These six tubes were incubated for one hour thereafter the broth in one set of three tubes was covered with about one inch of acriflavine emulsion and the other three were kept as controls. All were incubated

May 11 1938

Controls show heavy growth. Tubes treated with acriflavine emulsion remain clear the broth having taken on a rich yellow colour. Sub cultures were made from the latter for four days with the following results

	<i>B. Pyocyanus</i>	<i>Staph. Aureus</i>	<i>B. Coli</i>
May 11 1938	+	+	+
May 12 1938	+	+	—
May 13 1938	+	+	—
May 14 1938	+	—	—

The acriflavine diffuses sufficiently to inhibit growth. *B. coli* is killed in forty eight hours. *Staphylococcus aureus* in ninety-six hours and *B. pyocyanus* is still alive after that time—I am, etc.,

Dublin June 1 J WALKER TOMB M D, D P H

### Chicken-pox with Unusual Features

SIR—In view of the case reported by Dr J B Tilley and J F Warin (*Journal* June 11 p 1265) the following account of an unusual case of chicken-pox may also be of interest

A patient aged 25 contracted a cold which was followed four days later by the appearance of a rash on the face. At first glance the case appeared to be one of measles on account of the facial distribution of the rash, the catarrhal symptoms conjunctivitis photophobia etc. When the rest of the body was examined, however a few vesicles char-

acteristic of chicken pox were found on the left leg. On closer examination the rash on the face proved to consist of numerous tiny flat confluent nodules, some of which were already in the stage of turning into vesicles. In the course of the disease, which lasted for the unusual period of just over a month five or six crops were observed, and the skin of the whole body, particularly the scalp, was literally covered with vesicles some of which turned into pustules, whereas others ruptured and exuded a clear, sticky, evil-smelling fluid, which when dried up a few days later, formed thick scabs. Thus the different stages characteristic of chicken pox—namely, nodules, vesicles, pustules, scabs and desquamation—could be seen simultaneously. The highest temperature (102.6° F) was registered on the fifth day after the appearance of the rash. On that occasion small areas on the abdomen still free from chicken pox showed a scarlatiniform rash for not more than a day or two. The urine, which was examined daily with sulphosalicylic acid, revealed traces of albumin after the tenth day from the onset of the disease but the albumin disappeared a week later. The photophobia persisted almost throughout the disease and was caused by minute vesicles spread over the conjunctivae.

Cases of chicken-pox accompanied by a morbilliform or scarlatiniform exanthema are not unknown. These exanthemata are not due to true measles or scarlet fever but only represent a background of the chicken-pox. Although there exists theoretically the possibility of a simultaneous mixed infection, the present case did not seem to me to fall into this group. The most interesting features were (1) the long duration of the disease and the unusual number of crops, (2) the great number of vesicles and pustules, of which a few, perhaps through confluence, attained an unusual size (that of a walnut), and (3) the occurrence of slight albuminuria. A general toxæmia lasted only for a few days during the acme of the disease. Three adults unavoidably in touch with the patient contracted chicken-pox in a mild degree—I am, etc.,

London NW6 June 14

LEO SPIRA M D

### Aperients and Sulphanilamide

SIR—I have only just read a letter from Dr Joseph Jones, published in your issue of June 4 (p 1236), in which he reports that his colleague, called in to a case of puerperal pyrexia, was prevented from administering sulphanilamide because the midwife had recently given the patient a dose of Epsom salts. Dr Jones pleads that midwives should be instructed not to give to their patients in the later weeks of pregnancy any aperient containing sulphur. I would like to back his plea.

The commonest of these sulphur-containing purgative drugs and mixtures are Epsom salts, Glauber's salt, and compound liquorice powder. There are excellent saline and other aperients available which contain no trace of sulphur compounds. Liquid paraffin and Seidlitz powders are probably the safest aperients to give during the last month of pregnancy—I am, etc.,

Stepney E1 June 18

HARRY ROBERTS

### Treatment of Complications of Gold Therapy

SIR,—Those of us who have experience in the use of gold salts in the treatment of chronic arthritis are familiar with the unfortunate patient who develops a 'gold dermatitis'. Such a case was in my care for several months. The patient had a most extensive exfoliative dermatitis which affected the face, neck, trunk and limbs. After some months the skin cleared with the exception of that

of the nose which was so infected that the patient resembled the classical wooden soldier with a red patch on either cheek. A preparation of tannic acid and jelly was applied to the left cheek. A firm coagulum formed and after a week separation took place leaving a perfectly healed skin. The right side was then treated but for some reason the coagulum did not form so well and the healing took place in patches. The method was persisted in the jelly being reapplied to the parts where the coagulum was not satisfactory. Now only a small patch the size of a half penny remains with a thin coagulum which if it will remain in position long enough should give perfect healing. In view of the difficulty of treating this complication of aurotherapy any small advance seems worth recording.—I am, etc.

B. 5 June 17

JOHN B. BENNETT

### Nasal Sinusitis in Childhood

SIR—I was very pleased to read Mr James Crook's article in the *Journal* of April 30 (p 933). For twenty years I have been endeavouring to persuade the profession in Australia that treatment of sinusitis should precede operations on enlarged tonsils and adenoids. If this is done at least 75 per cent. of the tonsils and adenoids will recede. I long ago came to the conclusion that lavage was only of temporary benefit and up to 1913 performed radical operations freely. Since that date I have used diathermy and antrostomy. I prefer long wave to short wave diathermy, and I perform antrostomy by electro-coagulation as I find the opening is practically permanent if made large enough. On withdrawing the needle it is useful also to electrocoagulate the outer wall of the inferior turbinate. I adopt the same treatment for chronic sinusitis in adults. Diathermy has the great advantage that it acts upon the whole of the nasal mucosa. I use a low voltage, a frequency of one and a half millions and 200 to 500 milliamperes. For the first fortnight treatment should be for half an hour daily then three times a week for another fortnight and finally twice a week for a month.—I am, etc.

### Digital Clubbing

SIR—I was very interested in Dr E. Montuschi's memorandum in the *Journal* of June 18 (p 1310). The author tentatively suggests a causal relationship between the digital clubbing and the congenital lung cyst in the case reported. Is it not more likely that these two abnormalities are fortuitous in their association as it is well known that congenital anomalies are often multiple? I agree up to a point with Dr Montuschi as to the desirability of bronchography in these cases, in that it 'dots the T's' as Hanaud said, in any investigation of the lungs. I would only say that in a chronic suppurative lesion of the lungs or pleura the degree of clubbing is a rough measure of the extent of the disease and it is not at all common to find marked clubbing in, say, bronchiectasis without physical signs or suggestive changes in the radiographs. I can explain if not excuse my own omission (*Journal* March 19, p 614) by saying that at the time when I wrote my article there were no adequate facilities for bronchography at the hospital at which I was working.—I am, etc.

London W2, June 20

D. R. SEATON

### The Doctors' Cookery Book

SIR—I would like to congratulate those responsible for the article on *The Doctors' Cookery Book 1938* which appeared in the *Journal* of June 18 (p 1326) for having for the first time so far as I am aware taken vitamin D requirements into consideration in the establishment of their diet. With the possible exception of the case where calcium occurs in such foodstuffs as milk vitamin D would seem to be essential for the metabolism of this substance. Indeed calcium in the form of the ordinary salts such as the chloride carbonate lactate etc. appears to be incapable of efficient utilization in the absence of vitamin D. It seems likely also that the addition of vitamin D to the diet will lessen considerably the amount of calcium needed therein for correct nutrition. It is superfluous to refer to its anti-rachitic action. No arrangement occurs in Stiebeling's table as issued originally by herself or as referred to by Sherman for ensuring a supply of vitamin D in the diets recommended while Orr in his *Food, Income and Health* in employing Stiebeling's data as a standard for his diet for the production of optimum health omits any reference to vitamin D or its requirements. Curiously enough however (with out of course mentioning vitamin D) he has a section (p 41) dealing with rickets on the basis of its being a disease due to a deficient diet!—I am, etc.

Aberdeen June 18

J. P. MCGOWAN

### Doryl in Functional Urinary Retention

SIR—Professor F. R. Fraser (*Journal* June 18 p 1293) summarizing the therapeutic value of doryl and mecholol in relation to urinary retention that their value appears to have been established for retention following surgical operations, labour and lesions of the spinal cord. He says that Dr E. P. Sharpey-Schafer has demonstrated a rise of intravesical pressure ending in extrusion of the catheter following the intramuscular injection of 0.5 mg of doryl in a case of hysterical retention.

Since the publication of the work of Chassar Mont (*Lancet* 1937, 1 261) and of J. S. Maxwell (*ibid* 1937, 1 263) I have used doryl for urinary retention in a variety of neuropsychiatric diseases. It has been successful in acute organic reactions (deliria) and in chronic organic reactions—for example general paralysis and cerebral arteriosclerosis with hemiplegia—where some neurogenic factor may be at work. It has been equally successful in purely functional reactions such as hysteria, acute depression and the stupors. Catheterization always involves a risk of infection, and this risk is greatly increased in those cases of mental disorder where the patient, by resisting catheterization, may quickly break down the aseptic technique. In such cases it is most important to avoid the use of the catheter if at all possible. In female patients one can easily satisfy oneself that no organic obstruction is present but in male patients this is more difficult—for example a man of 57 suffering from schizophrenia suddenly developed acute retention coincidentally with an acute mental excitement, rectal examination showed no prostatic enlargement, but later, at operation a pedunculated middle lobe was found.

In all about a dozen cases of urinary retention which otherwise would have needed catheterization have been treated by an intramuscular injection of 0.25 mg of doryl. When this was unsuccessful a second injection half an hour later was sometimes effective, and usually led to a

simultaneous action of the bowels. Sometimes normal urinary control was established after one injection of doryl, in one case, after one success, doryl failed, in others the treatment has been repeated once or twice daily for as long as a week. No complications of note were observed. In three or four of the twelve cases there was no response to doryl.

I am grateful to Professor D. K. Henderson for permission to publish these observations which were made on patients under his charge in the Royal Edinburgh Hospital for Mental and Nervous Disorders.

—I am, etc.,

Edinburgh 10, June 20

HARRY STALKER

### Origin of Cancer

SIR—The statement by Dr J. V. Fiddian in the *Journal* of April 30 (p. 973) that 'conjugation occurs among the cells of malignant growths and was described by Bashford who observed it as identical with the process of conjugation seen in many protozoa' requires correction. Dr E. F. Bashford and Dr J. A. Murray read a paper on the conjugation of resting nuclei in an epithelioma of the mouse, an account of which appeared in the *Proceedings of the Royal Society* (1904, 73, 77). The observations described, however, were subsequently found to have been erroneous, and the original contentions of the observers were withdrawn the following year. The conjugation of cancer cells, in the words of Dr W. E. Gye, the present Director of the Imperial Cancer Research Fund, to whose courtesy I am indebted for the above information, 'is no longer believed in'—I am, etc.,

CHARLES M. BEADNELL,  
Surgeon Rear Admiral

Egham Surrey June 10

### Assistance to Medical Students from Austria

SIR—The letter of Professor John A. Ryle (June 11, p. 1286) raises questions of more than sentiment—a matter of principle is involved. While sympathizing with human suffering in any form, I yet do not see that the medical profession in England should be expected, or even asked, to bring to lives deprived of hope (according to Professor Ryle) the solace and comfort, not to mention pecuniary advantage, of a free home and a free medical education. I have known many a good man of our own race who has been more in need of such hope and comfort as a free medical education could provide, but who because of poverty, has had to look to some other sphere of human activity than medicine to earn a living. The lot of our own medical students is, from a financial standpoint, not a bed of roses, and I have personal recollections of existence for over three years on a diet of cocoa and dry bread, with an occasional kipper for variety, in order to save enough money to pay my hospital fees. Strange to say I do not remember any hospital dean, or anyone else, growing moist-eyed at my harrowing recital of inability to pay hospital fees!

This matter of refugees from certain Continental countries is fast becoming a political ramp, but I do not see why the medical profession of England should have to suffer for it—or are the men of the law equally troubled? If the deans of our large teaching hospitals feel it incumbent on them to offer Austrian or other refugees free medical education then I say that for every alien thus admitted let that hospital admit one of our own countrymen. If we must be generous to aliens in this

matter, then let us extend the same noble feeling to our own kith and kin. I have no doubt the London Hospital could find many suitable candidates for its generosity—I am, etc.,

Bournemouth, June 12

VINCENT NORMAN

### The Psychiatric Service

SIR—In view of the recent letters concerning the L.C.C. mental hospitals and higher qualifications the following points may be of interest.

1. A married man receives a commencing salary of £470 per annum.

2. From this is deducted £23 10s. for superannuation and approximately £2 10s. a month for meals whilst on duty. These are compulsory.

3. To gain promotion to the higher grades the D.P.M. and M.R.C.P. are essential. The cost of the former is £12 12s. and the latter £42, presuming that the candidate is successful on the first occasion of entry. It is not unreasonable to suggest that to gain the M.R.C.P. diploma the candidate should attend a clinical course at a teaching hospital, and belong either to a library or some learned society in order to have use of recent books and periodicals. Taking into account journeys to and from his course at a hospital an outlay of about £100 is necessary.

4. Residence near the hospital is compulsory. This means living in Greater London, where rents are high.

5. He is expected to be on the telephone, but this is omitted from the standing orders, so that income tax relief cannot be claimed.

6. Should he require a garage for his car at the hospital he will be charged £10 annually.

These points ignore the fact that an M.D. degree is also expected, which, in the case of London graduates, costs £21. It is surprising therefore that the L.C.C. continues to expect men of exceptional ability and attainments to enter a service paid at a lower level than an assistant in general practice—I am, etc.,

June 12

ANOTHER A.M.O.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In Convocation on June 14 it was agreed to confer the honorary degree of D.Sc. on Charles Gustave Jung, M.D., LL.D., professor of psychology in the University of Zurich. The degree will be conferred on July 30 during the International Congress for Psychotherapy, which will be held at Oxford from July 29 to August 2 under the presidency of Professor Jung.

The Vice-Chancellor recently unveiled a window in the Museum of the History of Science to commemorate gifts from the Mercers, Grocers, and Merchant Taylors Companies, the Royal College of Physicians of London and Friends of the Old Ashmolean. He referred to the link between the University of Oxford, the great City Companies and the College of Physicians. Dr R. T. Gunther, curator of the Museum, welcoming the representatives of the bodies whose coats of arms are incorporated in the window said that it served as a reminder of what Oxford owed to London whose Companies were helping them to continue the work that Ashmole contemplated but could not pay for and of the University's alliance with the College of Physicians, whose new President Dr Robert Hutchison they were glad to have with them on that occasion.

### UNIVERSITY OF CAMBRIDGE

The following medical degrees were conferred on June 18:  
M.B., B.Chir.—G. W. N. Dunn, P. A. T. Phibbs.

## UNIVERSITY OF LONDON

## WESTMINSTER HOSPITAL MEDICAL SCHOOL

D P Maguire of Beaumont College and R C Bradbury of Westminster City School have been awarded Entrance Scholarships on the result of an Entrance Scholarship Examination held on May 26 and 27.

## UNIVERSITY OF BRISTOL

The following candidates have been approved at the examination indicated

Final M.B. Ch.B.—See on II. Kathleen L. Brett, K. J. A. Carter, Margaret H. Davies, Edith M. D. Knox, G. R. E. Moxley, Margaret E. Morgan, R. H. Owen, Mabel W. N. Ingle, A. H. Wright, In Grade I only: W. H. G. Elliott, J. S. Richardson.

With distinction in First, Second and Toxicology.

## UNIVERSITY OF MANCHESTER

Dr H. K. Ashworth has been appointed Clinical Lecturer in Anaesthesia.

The University Council has appointed Alexander R. Todd D.Sc. of the Lister Institute of Preventive Medicine to succeed Dr J. M. Heilbron as Sir Samuel Hall Professor of Chemistry and Director of the Chemical Laboratories. Dr Todd graduated at Glasgow in 1925 and after holding various scholarships and research posts went to the Department of Chemistry in Relation to Medicine at the University of Edinburgh as Assistant to Professor Barter with a grant from the Medical Research Council and subsequently a Beit Memorial medical research fellowship. At Edinburgh he has worked on the chemistry of vitamin B and related compounds and on antihelmintics.

## UNIVERSITY OF WALES

## WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B. B.Ch. have passed the examinations in the subjects indicated.

Medicine—D. W. Abbe, O. D. Beresford, S. W. Bessick, D. C. Brown, D. G. Evans, W. G. Mile, A. H. Millard, Mary D. Owen, R. Tappin, Emily K. Williams (with distinction), Mary Williams.  
Pharmacology—D. I. Harries, A. B. J. Hill, Helen C. Hodges, R. T. Jones, G. A. Jones, J. V. Jones, H. L. Lloyd, J. E. Lloyd, M. E. Lloyd, S. Love, Brenda M. Mead, J. W. Morgan, D. G. Morris, R. E. Packer, H. V. Roberts, D. C. Taylor, C. E. Thomas, T. Walker, K. M. Wheeler.

The following candidates have attained the examinations in the examination indicated.

Tuberculous Diseases Diploma—H. L. Ackerman, A. Azmy, V. N. Krishna Iyer, H. S. Loharshi, S. Sen, A. V. R. Soliman, W. D. Sulastri, J. H. Vanarase, R. Viswanathan.

## UNIVERSITY OF EDINBURGH

The Senate has resolved to confer the honorary degree of LL.D. upon the Right Hon. Walter Elliot D.Sc. M.B. F.R.S. Minister of Health. It will be conferred on July 20 on the occasion of the installation of Lord Tweedsmuir Governor General of Canada as Chancellor of the University.

The Curators of Patronage have appointed Leysbourne Stanley Patrick Davidson M.D. F.R.C.P.E. Regius Professor of Medicine in the University of Aberdeen to the Chair of Medicine in the University of Edinburgh in succession to Professor W. T. Ritchie.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Council of the Royal College of Surgeons of England was held on June 9 when the President Sir Cuthbert Wallace Bt. was in the chair.

## Examiners

Mr Harry Stobie (Royal Dental Hospital) was re-elected a member of the Board of Examiners in Dental Surgery.

The following examiners were elected for the ensuing year:  
Dental Surgery (Surgical Section)—C. P. G. Wakeley, C. E. Statock, E. G. Slesinger, R. M. Vick, J. B. Hume, L. E. C. Norbury.  
In Medicine for the Licentiate in Dental Surgery—R. A. Rowlands, A. H. Douthwaite, R. A. Hickling.  
Fellowship—Anatomy—P. N. B. Odgers, H. H. Woollard, R. B. Green, E. P. Stubbs.  
Physiology—H. Hartnidge, J. Mellanby, D. T. Harris, A. St. G. J. McC. Huggitt.  
Under the Joint Examining Board—Elementary Biology—W. A. Cunningham, A. E. Ellis, S. R. B. Pask, W. Rushton.  
Anatomy—A. E. Cave, W. J. Hamilton, A. B. Apperton.  
Physiology—S. Wright, D. T. Harris.  
Midwifery—A. C. Palmer, A. F. Lack, T. B. Davies, W. Shaw.  
Pathology—W. G. Barnard, B. W. Williams, D. H. Patey, W. D. Newcomb.  
Diploma in

Health—Part I—H. M. J. Perry. Part II—C. Porter.  
Diploma in Tropical Medicine and Hygiene—Pathology and Medical Hygiene—W. P. MacArthur. Tropical Medicine and Surgery—N. H. Fairley. Diploma in Ophthalmic Medicine and Surgery—Part I—D. L. Davies, R. A. Greeve. Part II—A. Caddy.  
Diploma in Psychological Medicine—F. L. Golla. Diploma in Laryngology and Otology—Part I—E. Caraw Shaw, N. A. Jory.  
Part II—T. B. Lawton. Diploma in Medical Radiology—Part I—H. H. Frost. Part II—H. W. Davies. Diploma in Anaesthetics—H. L. G. Boyle. Diploma in Child Health—A. G. Maitland-Jones.

The Council decided that the Smithdown Road Hospital Liverpool which is already recognized under paragraphs 21 and 23 of the Fellowship regulations in respect of the resident medical officer be now recognized in respect of the first house surgeon (the resident surgical officer) and second house surgeon.

## Diplomas

Diplomas of Fellowship were granted to the following candidate:

L. McK. Crooks, K. K. C. Nambiar, J. A. Currie, R. W. Knowlton, G. H. Pearce, C. D. P. Jones, H. Ackers, W. S. McKenna, H. Goodwin, A. G. Leigh, H. W. Hall, B. J. Sanger, A. Innes, P. H. Newman, R. C. F. Catterall, F. R. R. Martin, J. Schorstein, S. G. Nardell, J. M. Brown, L. B. Joshi, A. C. Bruce, C. D. Donald, B. K. Rank, R. Cox, J. R. Armstrong, J. A. W. Bingham, A. M. Clarke, H. L. Davies, E. H. W. Guirard, J. C. Golightly, R. A. Hall, J. I. Hayward, J. Heslop, J. C. Hile, P. M. J. Morgan, G. H. Kitchen, J. Lannon, E. W. McMeeran, A. Rakot, S. C. Raw, M. G. Talwalkar.

A diploma of Membership was granted to Sidney Locket.

Diplomas in Anaesthetics were granted jointly with the Royal College of Physicians at London to the following candidates:

H. N. Andrew, J. N. Cave, D. C. Clark, J. F. C. C. Cobley, J. D. Conington, E. A. Danino, T. D. W. Fryer, J. S. Hayes, B. P. Hill, K. F. Hulbert, V. J. Keating, B. Law, on T. J. C. MacDonald, Marcelline R. Marhall, J. G. Mitchell, J. G. Murdoch, H. H. Pinkerton, Frances E. Radcliffe, J. A. W. Robinson, S. G. Shippard, Major A. M. Simson, R. A. M. C. H. L. Thornton, O. S. M. Williams, A. H. R. Yousef.

## Primary Fellowship Examination

The following have been successful at the First Professional Examination for the Diploma of Fellow:

H. Abd El Aziz, M. B. Ch. A. S. Aldi, M. B. BS. MRCS, A. C. Beale, M. B. Ch. B. R. Billington, MRCS, A. C. Bingle, R. Blunden, M. B. Ch. B. F. Braithwaite, M. B. Ch. R. MRCS, M. L. Burman, M. B. BS. M. Chaudhuri, M. B. BS. Joan Cleland, J. C. Coates, M. B. Ch. B. MRCS, A. J. Craig, M. D. H. J. Croft, M. B. BS. MRCS, C. H. Cullen, M. B. Ch. B. A. M. Desmond, M. B. BS. MRCS, F. P. Dewar, M. D. N. J. Dhondy, M. B. BS. Aileen M. Dickens, E. P. H. Drake, M. B. Ch. R. MRCS, H. H. Eddey, M. B. BS. G. M. Foote, M. B. Ch. B. R. G. Ginde, M. B. BS. J. D. Gray, M. B. Ch. B. M. W. Hicks, M. D. J. M. J. Jen, M. B. BS. J. H. A. Jewell, M. B. Ch. B. J. S. Joly, M. B. Ch. R. MRCS, R. A. King, R. L. Lammi, M. B. Ch. B. MRCS, L. R. Leach, M. B. BS. MRCS, O. Lloyd, M. B. BS. MRCS, D. A. Lowe, M. B. Ch. B. K. M. MacLeod, M. D. MRCS, J. E. Malcolm, M. B. Ch. B. N. S. Martin, M. B. Ch. B. N. L. Mehta, M. B. BS. Eleanor M. Mills, M. B. Ch. B. MRCS, S. V. Modi, M. B. BS. R. A. Mor, C. P. Nicholas, M. B. Ch. B. MRCS, H. A. Oatley, M. B. BS. R. Parkinson, M. B. BS. MRCS, D. S. Quill, M. B. Ch. B. D. Ranger, W. S. Rees, M. B. Ch. B. J. P. Ready, M. B. Ch. R. MRCS, D. A. Richmond, M. B. Ch. B. MRCS, P. W. S. Riley, M. B. Ch. B. P. A. Robinson, MRCS, M. S. C. Rudd, M. D. C. A. R. Schulenburg, M. B. Ch. B. H. K. Sett, M. B. F. A. Simmonds, MRCS, J. Singh, M. B. BS. W. E. Spring, M. B. BS. A. W. Stewart, MRCS, J. Swaney, M. D. BS. L. R. S. Taalor, W. Thompson, B. M. Truscott, M. B. BS. MRCS, A. K. Tulloch, M. B. Ch. B. Carolina M. van Dorp.

Professor P. B. Ascroft FRCS will deliver a Hunterian Lecture on "The Surgical Treatment of Arterial Hypertension" in the theatre of the College, Lincoln's Inn Fields, W.C. on Friday, July 1, at 5 p.m.

A special lecture on "The Mechanism of Peptic Ulceration: A Review of the Results of Experimental Investigations" will be delivered by Professor Frank C. Mann M.D. director of the Mayo Foundation for Medical Education and Research at the University of Minnesota in the theatre of the College on Friday, July 15, at 5 p.m.

Fellows and Members of the College are invited to attend Students and others who are not Fellows or Members of the College will be admitted on pre-arranged private visiting cards. Tea will be served before the lecture.

## Obituary

FRANCIS JOSEPH BAILDON, M.B., C.M.

Past President Lancashire and Cheshire Branch, British Medical Association

On June 13 Southport lost one of its best-known citizens and the medical fraternity a valued, respected, and much-liked colleague on the death of Francis Joseph Baildon.

A native of Newcastle-under-Lyme, Dr. Baildon graduated at Edinburgh in 1881. After holding the usual house posts he became resident medical officer at the Chalmers Hospital, Edinburgh. He came to practise in Southport in 1883. In 1889 he was appointed medical officer of the small hospital, holding about forty patients and dealing with simple cases only. This institution, then situated in

a back street, was the first step from the old public dispensary to a real hospital, and by his ability, zeal, and perspicacity Dr. Baildon exerted a great influence on the progress—scientific as well as popular—of this valuable development. In 1895 the Southport Infirmary was opened, and he became the senior "honorary medical officer," as the position was then known, in 1896. He retired from this office in 1919, when he was made senior honorary consulting

surgeon. For many years Baildon's opinion was sought in consultation by his colleagues. His powers of diagnosis and prognosis were very keen. He was always scrupulously careful to observe the highest ethical standards. He could not tolerate "show" or flattery, nor could he brook a pretence of knowledge on the part of his associates. Both in medical matters and in general affairs he always showed a discerning and well-ordered mind, which made his suggestions and advice of the highest value, whether in public meetings or in private affairs.

Baildon became a member of the British Medical Association in 1883, and took a keen interest in its work. He was elected chairman of the Southport Division in 1903, in 1906 becoming a member of the Executive Committee of this Division, and from that date till last year, when he insisted on retiring, he remained on the Executive Committee, either *ex officio* or by election. He was made a member of the Lancashire and Cheshire Branch Council in 1903, and again in 1912, remaining so, in view of being a member of the Central Council or as an elected member from the Southport Division till last year. In 1917–18 he was made president of the Branch, an honour which he received again in 1920 when the annual meeting of the Branch was held in Southport. He was the representative of the Southport Division to the Annual Representative Meetings in 1905, 1907, 1908, and from 1911 to 1931. He was elected to the Council of the Association in 1927 and retained his seat till his resignation in 1934. From 1920 onwards he served on the following committees: the Organization, the Journal, the Finance, the Grants, and the Science, and also on the Propaganda

Subcommittee. His last appearance in the council chamber at B.M.A. House was at the June meeting in 1936, when, accompanied by a colleague, he went up to press the invitation of the Southport Division to hold the Annual Meeting in Southport this year.

He was one of the founders of the Southport Medical Society in 1899, and always took a great interest in its activities. He particularly tried to increase the usefulness of the library of the society, acting as librarian for some years. He was president of the society for one term of a twelvemonth, and acted as honorary secretary for a few years. He was for some time honorary lieutenant of the Lancashire Voluntary Medical Corps, before the formation of the Territorial Army, and he also served as a temporary divisional surgeon at the V.A.D. hospital in Southport from 1915 to early 1919. For twenty-three years he served on the Southport Insurance Committee (N.H.I.), being elected as representing the municipal council.

In addition to these medical activities Baildon was always interested in scientific subjects. In 1890 he helped in the foundation of the Southport Society of Natural Science, which afterwards became the Southport Science Society. He gave lectures to that society on many occasions, was treasurer for a year or two, was on the council for many years, and was four times president. A good pianist, he was very fond of music, and took much interest in the Southport Orchestral Society, acting as president for some years as well as taking part in the organization as a member of the council of the society.

Baildon had a sound knowledge of literature. He was very widely read and took a keen interest in the development of the Southport library. He never entered into municipal politics, but readily accepted the invitation to become a co-opted member of the Library and Arts Committee of the municipal council in 1886. He served in this capacity from that year to the time of his death. Indeed, only four weeks ago—a week before the onset of his fatal illness—he attended the opening of the annual exhibition of modern arts organized by this committee. His judgment and advice, on the arts side as well as on the literature side of the committee's work, proved of great value. Socially he was well known to many people, as he had long been a member of the Savage Club. It can well be understood that such a man will be sorely missed in the town's life, but especially by his medical friends. Our sincere sympathy is felt for Mrs. Baildon and her daughter.

E. W. L.

ARTHUR HAWKYARD, M.D., LL.D.

Leeds has lost one of its most public-spirited citizens and one of its most-loved medical men by the passing at the age of 76 of Dr. Arthur Hawkyard, who died on June 17. He was a student of the old Leeds School of Medicine before its amalgamation with the Yorkshire College, and studied partly in Leeds and partly in Edinburgh, where he qualified by taking the diplomas in medicine, surgery, and midwifery in 1882. In 1907 he graduated as Doctor of Medicine at Durham University, having two years before manifested the catholicity of his interests by being called to the Bar. Before starting in practice in 1887 he acted as house-surgeon at the Rothwell Infirmary and he then worked for several years under Dr. Allen who at that time was in charge of the Union Infirmary at Leeds and to whose training Dr. Hawkyard was often heard to attribute much of his subsequent professional success. This success attended him from the time he started in practice in Hunslet and he secured the confidence and the affection of a very large circle of patients,

many of whom were his personal friends. As a loyal citizen of the place of his birth Dr Hawkyard entered fully into the public life of Leeds. He was a member of the Hunslet Board of Guardians for many years and a City Councillor for nine years. He was at the time of his death the son or lay magistrate of the City and a most regular attendant on the Bench where his work was highly prized by his fellow magistrates. He served a term as alderman and in 1930 with the cordial support of the members of all parties he was elected Lord Mayor and it was generally agreed that he carried out the duties and bore the responsibilities of that position with dignity and with great efficiency. During his tenure of office the University of Leeds conferred on him the degree of Doctor of Laws, on being presented for which honour he was happily described as a conspicuous representative of the good physician in general practice and a man of disinterested public spirit. Hawkyard was a man who never hesitated to express his views whether they were in harmony or at variance with those held by others and these views were always considered with respect. His cheerful disposition, his sound judgment, his genuine kindness of heart and his kindly sense of humour combined to build up a personality which will cause him to be greatly missed in the public life of Leeds and by a large circle of friends.

Dr Hawkyard joined the British Medical Association in 1892 was chairman of the Leeds Division in 1927-8 and served as Representative at the Annual Meetings in 1912 and from 1928 to 1936.

### THE LATE DR WINGRAVE

Sir James Dundas Grant writes

In the late eighties I accidentally met a smart dapper, square-jawed clear-eyed young man who told me he was teaching physiology at the Thomas Cooke School of Anatomy. This was Vitruvius Wyatt Wingrave and the casual meeting led to a valued and lasting friendship. I was then preparing for the Primary Fellowship and was led to enrol myself in his class. His claim that he ran through the whole subject of physiology if only up to standard of the Membership, in about three weeks was substantiated and I found his course a marvel of condensation without sacrifice of exhaustiveness or lucidity. It was a fortunate day for us all when I introduced him to my clinic and to my colleagues at the Central London Throat and Ear Hospital. His originality and his skill in practical pathology secured him a warm welcome and during his many years of service on the staff no one commanded in a higher degree the respect and affection of his colleagues. His reputation extended far beyond the immediate circle in which he worked and as an evidence of the appreciation of his ability it is sufficient to recall that the late Sir William Milligan that wise and outstanding otologist and laryngologist secured his co-operation in his great work on *Diseases of the Ear*.

"It was a cause of great regret to his colleagues that his state of health obliged him to give up professional work before the normal time but he had many sides and with a fastidious taste in art he took the greatest interest in all aspects of natural history and archaeology. His latter days were thus brightened by congenial researches which though they brought him no direct profit earned for him the respect and gratitude of those with whom he was immediately or distantly associated. In addition to the tokens of respect on the part of the inhabitants of Lyme Regis, where he died, Coventry where he was born, testified to its pride in its distinguished son by presenting him with the Freedom of the City. Those who knew Vitruvius Wyatt Wingrave were the better for having done so.

Dr ROBERT TAIT MCKENZIE to whom we briefly referred on May 28 (p. 1191) died suddenly of heart disease in Philadelphia on April 28. He had recently returned from the meeting of the Academy of Physical Education at Atlanta Georgia of which he was president. Born at Almonte Ontario in 1867 McKenzie took his M.D. at McGill in 1892. In 1904 he went to Philadelphia as professor and director of physical education in the University of Pennsylvania a post which he occupied until 1930. During the world war he held a commission in the Royal Army Medical Corps, and for a time was inspector of physical training for Kitchener's armies. His fame as an authority on physical culture was eclipsed by his distinction as sculptor with a flair for depicting the human body in action. His bronze medallion, The Joy of Effort to commemorate the Olympic Games at Stockholm in 1912 won him a silver medal from the King of Sweden and his exhibition of statuary in New York City in 1934 attracted national attention. A gentleman in the truest sense of the word, cultured, aristocratic, courteous and charming, McKenzie had made for himself a host of friends in Canada, in Britain, and in the United States.

Dr JOHN MALCOLM HARPER of Bath who died on May 30 at the age of 77 had had an active and very varied career. Born at Bathampton he was educated at Bath College, the London Hospital and the University of Durham. He qualified M.R.C.S. England in 1889 and he obtained the D.P.H. of Bristol in 1917. In addition to his medical practice in Bath he was surgeon to the police force, and was frequently a witness in celebrated cases including that of Hinks in 1934. For many years he was medical officer of health for the Bathampton rural district and was also medical officer for the later-formed Keynsham urban district. In his earlier days he had been an enthusiastic member of the Volunteer Force serving with the 1st Somerset Volunteer Battalion and attaining the rank of surgeon lieutenant colonel. He was a late honorary medical officer to the Eastern Dispensary and the Bath War Hospital and a medical examiner of recruits in the West Wessex area. In 1911 he joined the Bath Division of the British Medical Association. He was actively interested in several branches of Freemasonry and reached high rank in the craft. He was also widely known as an enthusiastic collector of antiques and lent to the Pump Room a valuable series of old naval pictures. He had married twice and is survived by his second wife and two daughters and a sister.

Norwich City Mental Hospital suffered a grievous loss in the untimely death of its medical superintendent Dr CHARLTON ROBERT FREDERICK HALL on June 7. A Lancashire man Dr Hall was educated at Birkenhead School and Trinity College Cambridge where he took the degrees of M.A. and B.Ch. afterwards proceeding to the London Hospital where he qualified M.R.C.S., L.R.C.P. In 1909 he married and was for some years in private practice at Shrewton Wilts. A serious operation prevented him from taking part in the great war, and during those years he was assistant medical officer at the Shropshire Mental Hospital. He was appointed to Hellesdon Mental Hospital in 1918 and became medical superintendent in 1935. He had been a member of the British Medical Association since 1908. He was a keen fisherman and excelled at all games and obtained his tennis blue while at Cambridge. He joined in hospital cricket and football matches for many years but perhaps golf was really his favourite game. A medical colleague writes: During the twenty years Dr Hall was at Hellesdon many great changes came about largely due to his interest and keenness to get away from the asylum atmosphere. He believed in as much liberty as was possible for his patients, and substituted individual clothing in place of drab uniforms thus giving to the patients fresh interest and a feeling of pride in their appearance. He was a pioneer in his administration of the admission

hospital in refusing to allow unsuitable patients to mix with the early and voluntary cases, the excellent results have fully justified his foresight. He was an eager supporter of all reforms, and was fortunate in having a most humanitarian committee to help him in his work. Many poor people in Norwich with mental trouble found in him a good friend. Dr Hall was also medical adviser to the Mental Deficiency Treatment Committee. Norwich has indeed lost one of its best-loved medical men, and it is difficult to believe he has gone from us. That charming voice, that kindly smile, will long be remembered by those colleagues and patients who loved and trusted him.

Dr GEORGE MALLACK BLUETT died on June 8 at Bath after a short illness at the age of 77. Although he had left Guildford for some years he was not forgotten by his colleagues and many friends there, who were sorry to hear of his death. His cheery personality and the good work he did for the British Medical Association endeared him to his medical friends. Educated at University College, London, and Paris, he took his M.R.C.S. in 1884, his L.R.C.P. in 1886, and L.S.A. in 1885. Dr Bluett was assistant medical officer to the Brook Fever Hospital at Woolwich. Later he became honorary physician to the Lying-in Hospital, Lambeth, and contributed papers to the Obstetrical Society's *Transactions*. During the great war he served as captain in the R.A.M.C. After the war he went to practise in Guildford, where he devoted much time and energy to B.M.A. work. He had been a member of the Association since 1887, and was honorary secretary of the Division for several years, and finally was chairman in 1932-3. Failing health caused him to retire to Bath. Our sympathy goes out to his wife, who survives him.—T. B. J.

We regret to record the death in an aeroplane accident of Mr CHARLES FRANCIS MASSY SWYNNERTON, director of tsetse research in Tanganyika Territory. During the past twenty years Mr Swynnerton had studied the tsetse fly problem. In 1921 he published a paper which threw new light on the possibility of reducing this scourge of Tropical Africa by controlling the types of vegetation, and two years ago he published a monumental work, *The Tsetse Flies of East Africa*.

JOHN JACOB ABEL, famous for his work on the chemistry of the ductless glands, has died at Baltimore at the age of 81. It is little more than a fortnight since he was elected a Foreign Member of the Royal Society, and in 1929 he received the gold medal for pharmacology and therapeutics of the Society of Apothecaries of London. Dr Abel, who had been for many years professor of pharmacology at the Johns Hopkins Medical School at Baltimore, was also a director of the laboratory for endocrine research there. His name will long be remembered for the researches which led to the production of adrenaline in a chemically pure state, and for the work which produced insulin in crystalline form. In 1932 he was president of the American Association for the Advancement of Science.

Dr THOMAS LATHROP STEDMAN, editor of *A Practical Medical Dictionary*, universally known as *Stedman's Medical Dictionary*, died in New York City on May 26 at the age of 84.

Dr VLADIMIR M. FORTUNATO, a prominent sculptor of medical models, left the Moscow Medical Museum in 1921 to take up a similar post at Johns Hopkins University. He was busily engaged preparing models for the New York World's Fair when he died of a heart attack on June 10 at the age of 53.

Dr HENRY TURMAN BYFORD, one of Chicago's leading gynaecologists who was honorary president of the International Congress of Gynaecology in 1896, died on June 5 at the age of 84.

The following well known foreign medical men have recently died: Dr EDUARD TRENDEL, an eminent orthopaedic surgeon of Stuttgart; Professor GAMPER, director of the psychiatric clinic of the German University at Prague, as the result of a motor accident, in which his wife was also killed; Dr ANTONIO CESARIS DEMEL, emeritus professor of morbid anatomy at Pisa, aged 72; Professor AUGUSTO GIANELLI, an eminent psychiatrist of Rome, aged 73; and Professor ATTILIO BONANNI, director of the Institute of Pharmacology of the University of Rome, aged 68.

## The Services

### IMS ANNUAL DINNER

The thirty seventh annual dinner of the Indian Medical Service took place in London at the Trocadero Restaurant on June 14, with the Director-General, Major-General E. W. C. Bradfield, C.I.E., O.B.E., K.H.S., in the chair. The official guests at the high table were the Marquess of Zetland, Secretary of State for India, General Sir Sydney Muspratt, Major-General W. Brooke Purdon, late R.A.M.C., Dr N. Hamilton Fairly, Dr N. G. Horner, Editor of the *British Medical Journal* and Dr T. S. Fox, Assistant Editor of the *Lancet*.

After the health of the King-Emperor had been honoured the chairman proposed the toast of 'The Service' and expressed the gratification of all at the presence of Lord Zetland and General Muspratt. He welcomed the junior officers of the Service, remarking that they had chosen a good life and great opportunities. India owed a heavy debt to the Indian Medical Service in the past, but the I.M.S. officers of to-day were doing as good work as their predecessors, and Sir John Megaw was recruiting first rate men to carry on the tradition. Major-General C. W. F. Melville, proposing the chairman's health, made a classification with humorous asides, of the members dining that evening into retired officers, serving officers, and new entrants. He said that General Bradfield was in himself the epitome of the I.M.S., a man whom everyone wanted to serve under. Lord Zetland, recalling a promise from the secretaries that no speech would be demanded from him, told a good story and declined to say more.

The last formal incident of a successful reunion was when the company stood for a moment in memory of Colonel John Anderson and Colonel J. J. Pratt.

The officers present at the dinner were

**Major Generals** Sir Robert McCarrison, I. M. Macrae, C. W. F. Melville, Sir John Megaw, Sir Frank Connor, H. R. Nutt, T. G. Paterson Fergus, Sir Cuthbert Sprawson, Sir Thomas Symons, Sir Leonard Rogers, and G. Tate.

**Colonels** H. Ainsworth, Sir Charles Brierley, H. H. Broom, H. M. Cruddas, H. R. Dutton, A. B. Fry, J. Fuller Good, T. A. Granger, C. R. M. Green, W. H. Leonard, R. G. Lynn, H. M. Mackenzie, F. P. Mackie, A. J. Macnab, A. A. McNeill, A. A. C. McNeill, Sir Richard Needham, C. H. Rheinhold, H. A. Stanger, Leathes, R. J. Taylor, R. G. Turner, J. Norman Walker, and C. N. C. Wimberley.

**Lieutenant Colonels** W. G. P. Alpin, F. J. Anderson, C. H. Barber, Norman Briggs, G. T. Buick, H. P. Cook, H. S. Cormick, D. G. Crawford, J. M. Crawford, H. J. M. Cursetjee, J. B. Dalzell Hunter, I. Davenport Jones, W. R. Dimond, F. F. Elwes, S. C. Evans, S. M. A. Faruki, J. K. S. Fleming, H. R. B. Gibson, E. S. Goss, V. B. Green, Armytage, F. Griffith, A. E. Grisewood, R. Hay, S. N. Hayes, W. L. Hurrett, J. M. R. Hennessey, B. Higham, H. Hingston, J. M. Holmes, E. V. Hugo, M. L. C. Irvine, H. H. King, J. B. Lapsley, J. C. H. Leicester, J. G. M. McCann, D. McDonald, R. F. D. MacGregor, H. M. MacKenzie, G. R. McRobert, S. A. McSwiney, E. C. G. Maddock, S. N. Makand, G. E. Malcolmson, W. A. Meerns, S. H. Middleton, West, T. R. Mulroney, Clive Newcomb, C. Newton Davis, H. K. Rowntree, J. D. Sandes, J. A. Sinton, V. C. R. B. Seymour Sewell, A. L. Sheppard, H. B. Steen, R. Steen, Ashton Street, W. A. Sykes, R. Sweet, C. Thomson, E. Owen Thurston, P. Verdon, E. L. Ward, E. E. Waters, H. Williamson, and R. E. Wright.

**Majors** H. C. Brown, J. A. Cruickshank, J. A. W. Ebdon, Sir Thomas Carey Evans, P. Heffernan, E. S. S. Lucas, V. B. Nesfield, C. G. Seymour, H. S. Waters, and R. A. Wesson.

#### NORTH PERSIAN FORCES MEMORIAL MEDAL

Edward Cochrane M.D. D.P.H. Medical Officer (Health) Gold Coast has been awarded the North Persian Forces Memorial Medal for 1937 for his paper on Tuberculosis in the Tropics published in the *Tropical Diseases Bulletin* 1937 vol. 4 Nos. 10 and 11. The medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by a medical officer of under twelve years' service of the Royal Navy Royal Army Medical Corps Royal Air Force Indian Medical Service or of the Colonial Medical Service.

#### KITCHENER MEDICAL SERVICE AWARDS

The Lord Kitchener National Memorial Fund Council has made medical service awards for 1938 as follows:

R. Andrew (Epworth College) for Middlesex Hospital Medical School Royal Army Medical Corps H. F. Omond (Halesbury College) for Guy's Hospital Medical School Medical Branch of the Royal Navy R. M. Phillips (Chesham College) for St. Thomas' Hospital Medical School Medical Branch of the Royal Navy J. F. Ward McQuaid (Stonhurst College) for St. Mary's Hospital Medical School Royal Army Medical Corps J. W. D. West (Chesham College) for Caius College Cambridge and St. Bartholomew's Hospital Medical College Medical Branch of the Royal Air Force and C. H. Holden (Wellington College) for St. John's University Medical School Medical Branch of the Royal Navy.

#### ALEXANDER MEMORIAL PRIZE

Major C. V. Macnamara R.A.M.C. has been awarded the Alexander Memorial Prize for 1937 consisting of a gold medal and a sum of £40. The prize is awarded annually to an officer of the Royal Army Medical Corps for professional work of outstanding merit.

#### LEISHMAN MEMORIAL PRIZE

Leutenant Colonel E. V. Whitby R.A.M.C. has been awarded the Leishman Memorial Prize for the year 1937 consisting of a silver medal and a sum of £40. This prize is awarded annually to an officer of the Royal Army Medical Corps or the Army Dental Corps for work of outstanding merit.

#### VOLUNTARY AID DETACHMENTS

The latest official returns of the progress made in the organization of Voluntary Aid Detachments show that 167 men's detachments and 1138 women's detachments comprising a total membership of 33616 have received recognition by the War Office. Since November of last year there has been an increase of 11 men's detachments and 41 women's detachments representing an increased membership of 1395. Of the present membership 1110 men and 5910 women have undertaken the mobile obligation.

The county areas in England which have a total membership of 500 and over are as follows: County of London 2019 East Lancashire 1812 Northolt 1586 Hampshire 1323 Surrey 1263 West Riding 1234 Cheshire 1188 Sussex 1110 West Lancashire 1096 Devonshire 1066 Somerset 1034 Essex 919 Kent 917 North Riding 792 Middlesex 726 Gloucestershire 600 Lincolnshire 559 Nottinghamshire 536 Berkshire 507.

In Scotland there are 167 detachments with a total membership of 318 of whom 100 are mobile members. There are 79 detachments in Wales, the total membership being 1852, of whom 354 are mobile members.

The present scheme for Voluntary Aid Detachments was inaugurated in 1923 and is designed to supplement the medical services of the Naval Military and Air Forces in time of war.

Mobile members are required to give an undertaking that in the event of the embodiment of the Territorial Army they are prepared to serve the medical services either at home or abroad. Immobile members undertake to serve within reach of their own homes.

## Medical Notes in Parliament

The House of Lords this week made progress with the Coal Bill and other measures.

The House of Commons discussed the Finance Bill the Education Estimates and foreign affairs.

The Parliamentary Medical Committee met on June 14. Sir Francis Fremantle in the chair, and appointed four representatives to attend the British Medical Association meeting at Plymouth. This will be the first formal representation of the Parliamentary Medical Committee at the Association's Annual Meeting. The committee also discussed on June 14 the desire expressed among panel practitioners for increases in remuneration to meet the increased complexity of their work. The committee decided to explore this subject with the British Medical Association. A communication was received and considered regarding the registration of medical qualifications in Grenada West Indies. Attention was given to the Infanticide Bill the Registration of Nursing Homes (Scotland) Bill and the Milk Bill which last is not now expected before the autumn. The committee will meet again on July 5.

#### Progress of Bills

In the House of Lords on June 20 Lord ALNESS introduced a Bill to amend the British Nationality and Status and Aliens Act 1914 to 1933 and it was read a first time. The Mental Deficiency Bill was brought from the Commons and read a first time. On the same day in the House of Lords the Children and Young Persons Bill and the Baking Industry (Hours of Work) Bill passed through committee. The Food and Drugs Bill was agreed to on report and the Prevention of Blindness (Scotland) Bill was read the third time and passed.

In the House of Commons on June 20 Sir ROBERT GOWER introduced the Protection of Animals (No. 2) Bill to amend the Protection of Animals Act 1911 and make it illegal to have possession of animals trained prepared or intended for fighting or baiting. The Nursing Homes Registration (Scotland) Bill and the Infanticide Bill were read a third time without discussion in the House of Commons on June 20.

#### Social Services in the West Indies

On May 14 the House of Commons in Committee of Supply considered the vote for the Colonial Office services. Mr. MALCOLM MACDONALD said he would not deny that there was room in the West Indies generally for improvement in many directions. A long-term policy of reconstruction had to be devised the first feature of which should be a steady expansion of the social and other services which could raise the standard of living of the people. There ought to be surveys of housing and more housing programmes. They must push ahead with the work already begun of improving the nutrition of the peoples and carry forward the work already started to develop really effective medical services in the colonies. The Government had decided to advise His Majesty that a Royal Commission should be appointed to inquire into the social and economic conditions in Barbadoes British Guiana British Honduras Jamaica the Leeward Islands Trinidad and the Windward Islands. He hoped to give the terms of reference and the names of the members of the Royal Commission at an early date.

#### Nutrition and Dietary Surveys

On May 14 Mr. COLVILLE informed Mr. Henderson Stewart that the Advisory Committee on Nutrition was carrying out extensive dietary surveys in England and Scotland. In

Scotland the work was in the hands of Professor Cuthcart and Sir John Orr, and it was expected that the studies would be completed in the course of the summer. Sir John Orr was also undertaking on behalf of the Carnegie United Kingdom Trust, a scheme of research to determine the relation between the diets and the state of development and health of children and adolescents. This research included a dietary survey carried out by a team of trained investigators. The experiments covered a period of twelve months and it was not expected that any results could be published until 1939.

### Annual Cost of Tropical Diseases

On June 14 Mr D. ADAMS asked the Chancellor of the Duchy of Lancaster as representing the Lord President of the Council, whether, in view of the fact that the report of the Medical Research Council 1936-7 quoted estimates to the effect that the direct financial loss due to malaria in India alone amounted to between £23,000,000 and £50,000,000 per annum, the indirect losses being still greater, and of the extreme importance of these losses, he would institute inquiries with a view to supplying reliable information on this matter with reference to all important tropical diseases. Earl WINTERTON said that it would be extremely difficult to obtain figures of any real value for the economic loss due to different diseases in tropical territories. Estimates such as those quoted by the Medical Research Council were of necessity very rough and based on incomplete data. They were useful only as illustrating in a general way the magnitude of the problem. It would certainly be true to say that the losses due to diseases other than malaria were also enormous.

### Service Patients in Mental Hospitals

On June 14 Mr RAMSBOTHAM informed Mr Kelly that the number of visits paid by the medical inspector attached to the Pensions Ministry Headquarters to institutions in Great Britain and Ireland in which Service patients were being treated was 135 during 1936, and 212 in 1937. In addition frequent visits were paid by local medical officers of the Ministry to mental hospitals from time to time in connexion with the admission of fresh cases but of these no central record was kept.

### Hospitals in Air Attack

On June 15 Colonel NATHAN asked the terms of reference to the committee appointed to inquire into certain questions relating to hospitals in the event of air raids. He also asked the Home Secretary to consider appointing as additions to the committee some person with experience as a member of the lay committee of the voluntary hospitals, and some person with experience as secretary, or similar executive officer of the voluntary hospitals. Mr GEOFFREY LLOYD answered that Sir Samuel Hoare did not formally appoint a committee to make a report on the organization of casualty hospitals but invited a small number of eminent persons in the medical world to consider the proposals which had been worked out by the Departments and to make recommendations to him on various matters. It was understood that this body could take into consultation anyone likely to be able to help them and it was suggested to the Home Secretary on their behalf that he should invite persons representing voluntary hospitals in the London area to take part in their deliberations. The Home Secretary would have done this but the Minister of Health would take over the supervision of the organization of war hospitals and had issued an invitation on the lines suggested.

### Analgesia at Childbirth

Dr SUMMERSKILL asked on June 16 whether the attention of Dr Elliot had been drawn to the recent conference of 7,000 delegates from women's institutes at the Albert Hall at which it was agreed by an overwhelming majority that analgesia at childbirth should be available for all mothers

who desire it, and whether he would set up an inquiry with a view to steps being taken which would meet the demand of these mothers.

Dr ELLIOT replied that when a doctor was in charge of a case the question of the administration of analgesics was within his discretion. As regards births attended by a midwife, the Central Midwives Board, the statutory authority regulating the practice of midwives, had resolved, following a report by the British College of Obstetricians that midwives who had received suitable instruction might, with adequate safeguards, themselves administer analgesics. It was within the powers of local authorities to provide the necessary apparatus as part of the equipment of the midwives whom they employed under the Act of 1936.

### Electrotherapy as Additional Benefit

On June 16 Mr DAVID ADAMS asked the Minister of Health to take steps to place electrical treatment at the disposal of rheumatic patients under national health insurance. Dr ELLIOT replied that the medical benefit to which insured persons were entitled was limited to services within the competence of general practitioners as a class. He had no power to extend the scope of the benefit. A number of approved societies, however, made provision by way of additional benefits for the electrical treatment in approved institutions of their members suffering from rheumatism.

### Recommendations of Voluntary Hospitals Commission

Dr ELLIOT stated on June 16 that a Provisional Central Council had been set up by the British Hospitals Association to consider the best methods of implementing the main recommendations of the report of the Voluntary Hospitals Commission. The Council was likely to issue a report towards the end of this year.

### Registrar-General's Statistics

Captain ELLISTON asked on June 17 whether the attention of the Minister of Health had been drawn to the belated publication of annual health reports, and whether he could arrange for earlier issue by the Registrar-General of the local vital statistics required by medical officers of health for the completion of such reports. Dr ELLIOT said in reply that every effort would be made to secure the completion and distribution of these statistics to medical officers of health at the earliest possible date.

### Advisory Committee on Mental Health Research

No Government grants have been made to county and borough councils during the past seven years for the purpose of research into the cause and treatment of mental disorder. An advisory committee has been set up with the approval of Dr Elliot by the Board of Control to consider the general question of research into mental disorders.

### Nursery School Provision

During the discussion of the Education Estimates by the House of Commons on June 20 Mr KENNETH LINDSAY said there were 105 recognized nursery schools, with an accommodation of 7,685. There had been an increase of 19 per cent on the year, but the total was still small, though many authorities made provision for children under 5 years.

**Hospital Finance**—On May 14 Mr D. ADAMS asked the Minister of Health whether he was aware of a growing body of opinion to the effect that British hospital finance was in need of fundamental overhauling and whether he would consider the possibility of instituting a corporation on the lines of the British Broadcasting Corporation including representatives of the central Government local authorities.

voluntary hospitals, and the medical profession to be put in complete charge of all hospital finances. Dr LLOYD said he was aware that opinions had been expressed on the lines indicated in the first part of the question but he could not commit himself to the view that the action proposed by Mr Adams would provide an appropriate solution.

*Sensitivity to Mustard Gas*—On May 14 Mr G. GRIFITHS asked the Home Secretary whether in view of the statement in the *Air Raid Precautions Handbook* No. 5 that all persons not previously exposed were about equally sensitive to mustard gas he would give details of the experiment by which the conclusions of Professor Marshall and others published in the *Journal of Pharmacology and Experimental Therapeutics* for 1922 that some people were 140 times as sensitive as others, were refuted. Mr LLOYD said he gathered that Mr Griffiths referred to a report published in 1919. The experiments described in that report were carried out with comparatively high concentrations of gas, whereas the statement in the handbook reflected recent similar experiments with lower concentrations. The difference in experience was probably due to that difference in concentration.

*Progress of Silicosis Investigations*—On June 14 Mr J. GRIFITHS asked what further steps it was proposed to take in the investigation into the problem of silicosis and other lung diseases in the anthracite coalfield of South Wales. Earl WINTERTON replied that as soon as the examination of the data and material recently collected at Ammanford had been completed the Medical Research Council proposed to extend the investigation to at least one further colliery. Thereafter a report on the whole of the findings would be prepared.

*Remuneration of Air Force Medical Officers*—Mr DENVILLE asked on June 16 if the Secretary of State for Air would give immediate consideration to the complaint of medical officers attached to the Royal Air Force recruiting depots of the insufficiency of their remuneration and of the ineffect of their engagement. Captain BALFOUR replied that consideration had been given to the representations made by the officers referred to but it had not been possible to modify their conditions of employment.

*Vaccine Therapy in Foot and Mouth Disease*—On June 20 Sir JOSEPH LEECH asked the Minister of Agriculture whether he was conferring with the Danish Government on the results of the foot and mouth vaccine experiments at Reims Island and whether His Majesty's Government was testing the efficacy of the vaccine. Mr MORRISON replied: I have seen reports on the active immunization of animals against foot and mouth disease in Germany. In a preliminary scientific account that has been published no details are given of the methods of preparation of the vaccine but it is stated that they will be published in the near future. The results of the use of the vaccine in the field will also be published later. The Foot and Mouth Disease Research Committee is aware of the work which has been carried out in Denmark and its recent application in Germany and is keeping in touch with the situation.

*Slum Clearance*—In England and Wales some 200,000 slum houses have already been demolished, closed or made fit and a further 250,000 occupied by about 1,000,000 persons still fall to be dealt with. Action has been initiated in respect of about 170,000 of these. In the twelve months ended April 30 last over 70,000 replacement houses were approved as compared with about 59,000 approved in the preceding twelve months.

#### Notes in Brief

Six cases of small pox were notified in England and Wales in 1938 up to and including the week ended May 21, 1938. During the quarter ended March 31, 1938 one death was assigned to small pox.

With regard to the suggested legislation under which local authorities are to have power to decide whether or not there shall be compulsory pasteurization of milk sold in the area under their control the Ministry of Health and the Ministry of Agriculture are in consultation with representatives of the associations of local authorities concerned.

The total number of houses completed by private enterprise in England and Wales with State assistance from 1919 up to March 31, 1938 was 426,276.

On May 31 Mr RAMSBOTHAM informed Viscountess Astor that 7,776 ex-service men in receipt of disability pensions died in the twelve months ended last March their mortality rate being 17.9 per 1,000. For the general male population of corresponding ages in England and Wales the mortality rate for the same period was approximately 13 per 1,000.

The number of houses required in Scotland to replace unfit houses and to put an end to overcrowding is about 250,000. Houses built by local authorities specifically for these purposes in 1937 numbered 12,857.

## Medico-Legal

### CRIMINAL NEGLIGENCE OF AN UNQUALIFIED PRACTITIONER

A practitioner of medicine qualified or unqualified, must bring reasonable skill as well as care to his treatment of a patient and if he attempts a task which is obviously far beyond his powers and harm results, his negligence may be regarded as so flagrant as to be criminal.

A school teacher aged 23 who suffered from diabetes was for four years on a strict diet and insulin. On the advice of a friend she consulted an osteopath and radiologist named Herbert Jones who said she had not got diabetes and never had had it but was suffering from anaemia. He advised her to starve herself for four days and take nothing but orange juice. This she did discontinuing her insulin and in three days she had lost seven pounds. Her father telephoned to Jones and he replied that she should continue with the treatment until she saw him in a few days time. On that day she went into coma and although she was taken to hospital she died a week after consulting Jones. He was sent for trial at the Gloucester Assizes before Mr Justice Charles and Dr Thomas Haslett a pathologist said that cessation of the insulin treatment would lead to death. Jones giving evidence in his own defence said he had found no objective symptoms of diabetes but had found symptoms of anaemia. He put the patient on a four days fast with hot water and orange juice as a preliminary clearing of the system for further treatment. He had intended getting a medical friend to carry out tests for diabetes. In answer to the judge he said that he had not put the patient off insulin. In cross examination he admitted that he had no experience of diabetes and that he had made a mistake in his diagnosis in view of the absence of objective symptoms. Asked by the judge why he had not sent her back to her doctor when he heard she had been treated for diabetes, he replied that she had not come to him as a diabetic. He said he had taken up the science of healing twenty three years ago when he had cured by the laying on of hands a man who was dying of consumption.

The judge remarked that Jones's conduct was a danger to the State and to the public and that if it had not been for his good character he would have been bound to send him to prison for a long term not only to correct him but also to deter others who might be likely to undertake the treatment of sick folk without proper knowledge. He sentenced Jones to six months in the second division.

# INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 11 1938  
 Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)  
*Figures of Births and Deaths recorded under each infectious disease are for* (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland  
 A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)	
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)	(i)	(b)

† Cases in Belfast alone  
 † Death from puerperal sepsis

## EPIDEMIOLOGICAL NOTES \*

## Small pox

The notification of small pox in England and Wales is the case reported at Gravesend on June 9 referred to in this column last week.

During the week ended June 11 there were in Hong Kong 6 cases of small pox with no deaths. In the same week 5 cases and 4 deaths were notified in Burma 42 cases and 35 deaths in Calcutta 137 cases and 35 deaths in Bombay (Presidency), 13 cases and 6 deaths in Madras (Presidency), 84 cases and 12 deaths in Sind. In the same week in the Central Provinces 38 (102) cases and 11 (25) deaths from plague were reported and in the North West Frontier Province 45 (9) cases and 10 (7) deaths. In Indo-China 35 cases were notified in Tonking compared with 85 in the previous week (ended June 4). In the week ended June 4 in the United States of America 425 cases of small pox were reported.

## Enteric Fever

During the week under review there were 20 notifications of enteric fever in England and Wales compared with 31 in the previous week. Of these 2 (4) were in London—1 each in St. Marylebone and Wandsworth. In Scotland 3 cases of typhoid fever were notified—1 each in Glasgow, Berwick County and Motherwell and Wishaw. There have been no fresh cases of typhoid in the Hawick outbreak during the week, and up to the time of going to press 5 deaths have been recorded.

## Diphtheria and Scarlet Fever

In England and Wales notifications of diphtheria dropped during the week under review from 986 to 912, and in London from 139 to 113. There was a slight increase in notifications for Scotland but a decrease in Eire and in Northern Ireland. Deaths in the 126 Great Towns of England and Wales fell from 24 to 23, but in London they rose from 2 to 4. Of the 23 deaths from diphtheria recorded in the 126 Great Towns 2 each occurred in Birmingham (0) Newcastle under Lyme (1), and Stoke-on-Trent (1). There was 1 death from diphtheria in Scotland during the week—in Dundee. A fall in the notifications of scarlet fever was noted in England and Wales during the week under review—1967 compared with 1743—also in London where 149 cases were recorded as against 188 in the previous week. The figures for England and Wales however were slightly in excess of the median value for the last nine years but for London they were less. In the Great Towns of England and Wales 4 deaths were recorded from scarlet fever compared with 6 in the previous week, there were no deaths from scarlet fever in London during the week. Notifications in Scotland rose from 396 to 420—there were no deaths. In Eire the figures fell from 103 to 74, with 1 death, and in Northern Ireland from 91 to 66.

## Primary and Influenzal Pneumonia

Notifications of primary and influenzal pneumonia tell appreciably in England and Wales and in London during the week under review—from 919 to 801 in England and Wales and from 72 to 63 in London, the figure for England and Wales is well below the median value for the last nine years while that for London is slightly less. Fewer deaths from influenza were reported in England and Wales and London during the week but in Scotland the deaths rose from 1 to 3. In the West Riding (Yorks) 121 (107) cases were notified of which 38 (25) were in

the Administrative County 34 (35) in Sheffield 19 (19) in Leeds 10 (10) in Bradford. In Warwickshire there were 49 (59) cases of which 38 (36) were in Birmingham. Of the 120 (180) cases reported in Lancashire 27 (53) were in Liverpool and 19 (43) in Manchester. There were 30 deaths from influenza in the 126 Great Towns of England and Wales during the week, of these 4 (3) were in Manchester and 2 each in Birmingham (5) and Bristol (1). In Scotland 210 cases of primary pneumonia were notified compared with 240 in the previous week, there were 11 cases of influenzal pneumonia—compared with 7 in the previous week—and 3 deaths 2 in Glasgow and 1 in Ayr. In Eire there were 15 deaths from pneumonia of which 10 (8) occurred in Dublin and 3 (2) in Limerick. There were 15 (10) deaths from pneumonia in the ten principal towns of Northern Ireland during the week 11 (6) in Belfast and 2 each in Londonderry (1) and Lurgan (1).

## Measles and Whooping-cough

In the 126 Great Towns there were 12 deaths from measles compared with 20 in the previous week, of these 2 each occurred in Tottenham (1) Leeds (1) Newcastle-upon-Tyne (1) Sheffield (1) and 1 each in Twickenham (0) Bury (0) Salford (0) Exeter (1). There were no deaths from measles in London but there was a slight increase in some of the notifications during the week 660 cases were reported from the LCC elementary schools compared with 812 in the previous week. The average daily admissions to the LCC fever hospitals were 33 compared with 31 in the previous week, and the number of cases of measles under treatment in these hospitals on Friday June 10 was 1108 compared with 1171 on June 3. On the same day there were under treatment in the LCC fever hospitals 1014 (1012) cases of diphtheria 800 (824) cases of scarlet fever 268 (259) cases of whooping cough. Notifications for the week ended June 11 in the eleven metropolitan boroughs in which measles is notifiable were 348 (341) distributed as follows: Battersea 39 (14) Bermondsey 8 (8) Finsbury 24 (13) Fulham 61 (23) Greenwich 67 (96) Hampstead 21 (28) Lambeth 32 (61) St. Pancras 47 (36) Shoreditch 11 (18) Southwark 12 (14) Stepney 26 (30). In Scotland 309 cases of measles were notified compared with 271 in the previous week, the figures for Glasgow were 76 (65) Lanark County 67 (30) Dundee 36 (68) Falkirk 35 (25) Edinburgh 29 (17) Dunfermline 25 (—), Kirkcaldy 21 (43) Aberdeen 10 (14). During the week there were 4 (10) deaths from measles in the 16 principal towns of Scotland, of these, 1 each occurred in Glasgow (2) Dundee (4) Aberdeen (1) Coatbridge (0). In Eire and Northern Ireland there were no deaths from measles.

In England and Wales there were 11 (13) deaths from whooping cough during the week under review, there were no deaths in London. In Scotland 56 cases of whooping cough were notified compared with 102 in the previous week while there was only 1 death—in Dundee. In Northern Ireland 17 (18) cases of whooping-cough were recorded, with 2 deaths—both in Belfast.

## Cholera

During the week ended June 11 84 cases of cholera were reported in Shanghai and in Hong Kong 9 cases and 6 deaths. In the same week in Burma 9 cases and 8 deaths were notified in Calcutta 84 cases and 30 deaths in Bombay (Presidency) 51 cases and 34 deaths in Delhi 8 cases and 4 deaths. The cholera epidemic is still on the increase in the North-West Frontier Province of India and in Sind but in the Punjab and in the Central Provinces the situation is reported to be slightly better. In the Punjab 569 deaths were recorded in the week ended June 4 compared with 720 in the previous week while in the Central Provinces during the week under review 1,954 cases and 1,024 deaths were notified, compared with 2,528

\* Except where otherwise mentioned figures in parentheses refer to the week preceding the one under review.

cases and 1,334 deaths in the previous week. In Cawnpore (United Provinces) in the week ended June 11, 40 cases of cholera and 14 deaths were reported. In French Indo-China during the same week 158 cases were notified in Annam 305 in Tonking, 11 in Hanoi.

#### • Plague

During the week ended June 11 there were 4 cases of plague and 2 deaths in Burma in British India in the same week 5 cases and 2 deaths were notified in Bombay (Presidency) and 14 cases and 3 deaths in Madras (Presidency).

#### Typhus

During the week ended June 11, 2 cases of typhus were notified in Alexandria and 3 in Cairo, in Palestine in the same week 9 cases were reported—2 at Haifa, 7 in the rural districts. During the week ended June 4 169 cases and 24 deaths were reported in Morocco, mainly distributed as follows: Marrakesh, 42 cases, 1 death; Chaouia 41 cases 9 deaths; Oued-Zem, 24 cases, 6 deaths; Dukkala 16 cases 2 deaths; Rabat, 15 cases, 2 deaths; Casablanca 9 cases 1 death. During the week ended May 28, 88 (100) cases of typhus and 1 (4) death were reported in Poland. They were distributed mainly as follows: Stanislawow, 18 cases, 1 death; Lwow 15 cases; Wolhynia 14 cases; Wilno 13 cases; Polesia, 8 cases and 7 each at Nowogrodek and Tarnopol. During the week ended May 14 in the United States of America 25 cases of typhus were notified: Georgia 8, Alabama 7, Texas 6, Maryland 2, California 1, Florida 1.

## Medical News

Sir James Barrett KBE who presided over the Melbourne Meeting of the British Medical Association in 1935 has contributed this year an interesting series of articles to the *Melbourne Herald* containing reminiscences of his long and varied career in medicine and public life.

The annual dinner of the Cambridge Graduates Medical Club will be held at Corpus Christi College, Cambridge on Friday July 8 at 7.45 p.m. with Sir Walter Langdon Brown in the chair. Annual meeting at 7.15. Price of dinner (including wines and gratuities) 12s. 6d. The honorary secretaries are Mr W. D. Doherty and Dr L. E. H. Whitby.

The fifth conference of the Open Door International for the economic emancipation of the woman worker will be held at Girton College, Cambridge, from July 24 to 29. The subjects for discussion will include modern problems of maternal health, nutrition policies as they affect the woman worker and industrial hygiene and the woman worker.

The next meeting of the German Ophthalmological Society will be held at Heidelberg from July 4 to 6. Further information can be obtained from the secretary, Professor Wagenmann Heidelberg.

The summer meeting of the Association of Clinical Pathologists is being held at Oxford to-day (Saturday June 25). From 9 a.m. to 10 a.m. there are demonstrations in the pathology department of Radcliffe Infirmary by Dr J. G. Greenfield (removal of brain and cord), Dr A. G. Shera (an electrical rotary saw for use in post mortem work) and Dr A. H. T. Robb Smith (technique of exposure of accessory sinuses). From 10 a.m. to 1 p.m. at a scientific meeting at Nuffield Institute Sir Bernard Spilsbury speaks on the technique of the medico-legal post mortem followed by Dr Robb Smith (uses of fresh preparations in post mortem work) and Dr E. Wordley (status lymphaticus).

Doctors Day will be held at the Lord Mayor Trelour Cripples Hospital and College Alton on Wednesday July 6, the principal guests being Lord and Lady Horder.

The ninety-seventh annual meeting of the Royal Medico-Psychological Association will be held in the King's Hall, Ilkley, on Wednesday, Thursday, and Friday, July 6, 7 and 8. The council and committees will meet on Tuesday, July 5. The presidential address will be delivered at Scalegate Park, Burley-in-Wharfedale, on July 6, at 2.30 p.m., and the annual dinner of the Association will be held at Wells House Hotel, Ilkley, at 7.15 p.m. for 7.45 p.m. the same day.

The second International Congress of Anthropological and Ethnological Sciences will be held at Copenhagen from August 1 to 6 under the presidency of Dr Thomas Thomsen. It will be followed by a tour of Denmark. Applications for membership should be sent to the treasurer of the congress, Nationalmuseet 10 Ny Vestergade Copenhagen K. Thos Cook and Son Ltd Berkeley Street London W, have been appointed by the Danish committee as official travel agents.

An international course on malariaology will be held from July 18 to September 17 at the Institute of Malariaology in Rome. The lectures, which are intended for foreign practitioners will be delivered in French. Further information can be obtained from the director of the Institute, Professor G. Bastianelli, Policlinico Umberto I Rome.

The trustees of the Lady Tata Memorial Fund announce that on the recommendation of the Scientific Advisory Committee they have awarded the following grants and scholarships for research in blood diseases with special reference to leukaemia, in the academic year beginning on October 1, 1938. Grants for research expenses or for scientific assistance: Dr Julius Engelbreth-Holm (Copenhagen), Dr M. P. J. Guerin (Paris), Professor Karl Jirmay (Budapest), Professor James McIntosh (London), Professor Eugene Opie and Dr J. Furth (New York), Dr Georg Weitzmann (Leipzig), Dr Joachim Wienbeck (Breslau). Whole time scholarships: Dr Jorgen Bichel (Aarhus Denmark), Dr Edoardo Storti (Pavia, Italy). Part time scholarship: Dr Werner Jacobson (Cambridge).

Dame Florence Barrie Lambert M.B. distributed the prizes and certificates at the London (Royal Free Hospital) School of Medicine for Women on Wednesday June 15 and in her address to the students spoke of the many opportunities for clinical work open to newly qualified women compared with the few when she entered medicine. Nowadays, she said, there were all sorts of good posts open equally to women and men since the passing of the Poor Law Act of 1929 and the taking over in the following year by the London County Council of a large number of hospitals accommodating 40,000 patients. After the ceremony there was a garden party at which the dean Miss E. Bolton, members of the council and students entertained their guests.

Medical practitioners are asked to note that the out-patient department of the National Hospital for Diseases of the Nervous System, Queen Square, W.C. will be closed from July 11 to 19 inclusive. Queen Mary has consented to open the new wing of the hospital on July 19 at 3 p.m.

Professor H. Eppinger and Dr E. Risak have been appointed editors of the *Wiener klinische Wochenschrift*.

Professor Hermann Stieve of Berlin has been nominated president of the international committee for the improvement and unification of anatomical terms.

The King has appointed Dr Percy Selwyn Selwyn Clarke (Director of Medical Services) to be an Official Member of the Legislative Council of the Colony of Hong Kong.

Professor Reynaldo dos Santos of Lisbon was awarded the Violet Hart gold medal for his work on vascular surgery on the occasion of the Surgical Congress of the South Eastern United States.

A monument to Dr Albert Calmette has recently been unveiled at Nice.

## Snoring

Mr J H BADCOCK FRCS (Bury St Edmunds) writes  
Zs patient (*Journal* June 18, p 1348) should ask his dentist to make him a mouth 'valve' or 'shield' which, worn between lips and teeth will make mouth-breathing impossible. If the mouth falls widely open chin support may be necessary in addition the nose must be patent. A simple device for keeping the nares open is made as follows: take a piece of rubber tubing of a diameter to fit the nostrils comfortably and about 2 inches long, double it and with scissors cut a 'window' in the middle about  $\frac{1}{2}$  inch wide leaving about  $\frac{1}{4}$  inch of the circumference intact, thus forming to fit the nostrils two tubes connected by a narrow strip across the septum.

## LETTERS, NOTES, ETC.

## Birthday Honours Addendum

The names of two recipients of Birthday Honours were omitted from the list published in our last issue at p 1329. Dr James Laidlaw Maxwell, General Secretary of the International Red Cross Committee for Central China, is created CBE (Civil Division) and Mr Janardan Sitaram Vaidya, assistant surgeon, Medical Department, Somaliland Protectorate, Honorary MBE.

## Bed-bug in the Human Ear

Dr N VERE-HODGE (St George's Hospital) and Mr A W McKENNY HUGHES (British Museum Natural History) write: On June 6 a middle-aged woman attended St George's Hospital complaining of discomfort and a feeling of fullness and noises in one ear. She was awakened and prevented from sleeping by these symptoms. She did not complain of pain. When examined she was clean in her person and no other external parasites were seen. Both ears were seen to be full of wax and on washing out the affected side much wax appeared followed by a live insect—a male specimen of *Cimex lectularius* Linn., the bed-bug. This occurrence is so rare—in fact this is thought to be the first record in Great Britain—that it seems worth reporting.

## "The Evolutionary Theory"

Colonel G F ROWCROFT DSO (Coonoor, S India), in the course of a letter dated March 28 writes: The answer to Surgeon Rear-Admiral Charles M Beadnell (*Journal* March 5 p 550) will be found at page 44 of *Why be an Ape?* by A London Journalist (Marshall, Morgan, and Scott, price 2s 6d). In 1908, Haeckel published in a pamphlet, *Das Menschen Problem*, diagrams showing the embryos of man and of various types of apes for comparison. Dr Arnold Brass in 1908 in another pamphlet asserted that the diagrams were inaccurate, some being deliberately falsified. Haeckel's reply in the *Münchener Allgemeine Zeitung* of January 1909, contained the following admission: 'To put an end to this unsavoury dispute I begin at once with the contrite confession that a small number of my embryo diagrams are really forgeries in Dr Brass's sense. I should feel utterly condemned and annihilated by the admission were it not that hundreds of the best observers and biologists lie under the same charge. The great majority of all morphological, anatomical, histological, and embryological diagrams are not true to nature but are more or less doctored, schematized and reconstructed.' The London Journalist continues: 'Who among the opponents of evolution has brought any such sweeping indictment of the integrity of science as this admission by one of the world's foremost biologists?' I myself plead guilty to one error. I am afraid I said that Haeckel admitted that many of his illustrations were faked. He actually said that only a small number were. But the falsification of even only one in a chain of such evidence destroys the value of the whole of it. From the above it will be seen that to speak of Haeckel's indignant refutation is hardly accurate, as he has admitted that the 'venomous charge' is a perfectly true one. Your correspondent like many others is evidently unable to see Haeckel's numerous fallacies which only shows that he must be a very subtle writer. Everyone will agree that he has made his great work, *The Evolution of*

Man most attractive and specious, hence its great sale, though a large sale of any work in no way betokens its accuracy, as anyone can see for himself if he will call to mind many books of pure fiction. Where is the inconsistency in believing in other forms of progress while denying the evolution of man from the amoeba? They are not necessarily related in any way. And must there really be retrogression before progress?

## Health Survey of Kedah

Kedah is a State lying on the western coast of the Malay Peninsula. Its area is roughly three thousand square miles, its population nearly half a million. Rainfall is copious, temperature and humidity uniformly high. The terrain comprises a flat coastal belt devoted to rice growing, and a hilly interior, occupied to a considerable extent by large rubber estates, although extensive areas are still clothed in primeval jungle. The inhabitants, except labourers on the rubber estates imported from India, are nearly all Malay. A *Health Survey of the State of Kedah* is a comprehensive report of the investigations undertaken by Dr W J Vickers and Dr J H Strahan during 1931 and 1936. The survey is divided into six parts, one of which is devoted to nutrition. The authors found that the diet of the Malay is deficient in energy value, in good class protein, and in vitamin B, especially in the remoter districts. It is suggested that the intake of vitamin B might be supplemented by instruction in the use of rice polishings as an addition to soup and by the consumption of such leguminous foods as dhal and soya bean. It is also suggested that the insufficient intake of fat might be remedied by the inclusion in the dietary of animal fat, red palm oil and eggs. The authors maintain that a definite degree of subnutrition exists among the general population. The rural Malay lives on the verge of safety. With short hours of work and the maximum amount of rest ill effects are not always apparent, but any increased effort as for example, strenuous road-making work appears to induce mild symptoms of such deficiency diseases as beriberi. The value of the report is enhanced by the inclusion of maps, charts, and excellent photographs, all relevant.

## Medical Postage Stamps

From Holland has recently arrived an artistically pleasing set of five stamps, two of which are of medical interest. Boerhaave, the bicentenary of whose death is commemorated this year, is portrayed on a 12½ plus 3½ cent light blue stamp, and Rembrandt, whose 'Anatomy Lesson' in The Hague is probably the best known medical painting in the world, adorns the olive green 5 plus 3 cent value.

## Prontosil Booklet

We have received a booklet entitled 'Prontosil' from Bayer Products, Ltd., which is a well documented survey of the new chemotherapy. It runs into some seventy-one pages and the ten chapters are divided into three sections: (1) Experimental Findings, (2) Clinical Experiences, and (3) Therapeutics. Copies can be obtained on application to Bayer Products, Ltd., Africa House, Kingsway, London, WC2.

## Disclaimers

Mr T P NOBLE FRCS, Dr A P BROWN and Dr W B SHAW of Ebbw Vale Mon write: In an article which appeared in a London daily paper and a South Wales evening paper reference is made to us in connexion with an operation performed at Ebbw Vale General Hospital. We were greatly distressed on reading the article, which was written entirely without our knowledge or consent, and steps have been taken to prevent any repetition.

Dr SUSAN BEATTY wishes to disclaim any responsibility for the unwelcome publicity given by newspapers to a simple appendicectomy which she performed in mid Atlantic on the *Letitia*.

## Corrigendum

In the reply to an income-tax inquiry by 'Major R A M C' in last week's *Journal* (p 1348) the word 'blamed' in the last line but one should read 'allowed'.

during oral liver treatment, for the anti-anaemic factor is only freed for absorption in acid digestion. After discharge from hospital the patient should continue to take 150 to 200 grammes of raw liver twice weekly, the blood should be examined every two to three weeks, and a watch should be kept for numbness, paraesthesia, or stiffness of the limbs.

#### 543 Heart Failure and Hyperpiesis

A RUHL (*Zbl inn Med* April 2, 1938, p 242) discusses the problem of heart failure in patients suffering from high blood pressure. As a result of a number of experiments carried out on a Starling heart-lung preparation he states that (1) the increased peripheral resistance brought about by high blood pressure imposes an unphysiological burden on the heart and brings about a disproportionate increase in its oxygen consumption, (2) the heart undergoes definite dilatation as a result of high blood pressure, and (3) the peculiar lactic acid metabolism of the normal heart—absorption of lactic acid from the coronary circulation instead of a liberation of lactic acid as is the case in skeletal muscles—is not affected by hyperpiesis. As Ruhl points out, these conclusions only apply, strictly speaking, to the isolated heart-lung preparation and not to the heart under the control, as it actually is in the body, of the sympathetic and parasympathetic hormones, adrenaline and acetylcholine. Experiments in this direction, however, would seem to show that any alterations due to these factors are only quantitative and not qualitative, so that the fundamental validity of his conclusions remains unaffected.

#### 544 Acute Epidemic Phrenic Neuralgia

J TORGENSEN (*Nord med Tidsskr* April 9, 1938, p 572) gives an account of a small epidemic of phrenic neuralgia in a rural area of Norway with a population of about 4,000. Between August 9 and October 27, 1937, he observed eight cases with such a uniform clinical picture that they could be regarded as the units of one and the same epidemic, although the patients lived far apart and had had nothing to do with each other. Their ages ranged from 12 to 48, and the sexes were equally represented. The onset of the symptoms was sudden, with fever and pain in one or other of the shoulders. After a short interval violent pain set in, being referred to the lower part of the chest and the whole of the abdomen down to the iliac fossae. The symptoms were alarming and simulated those of cholecystitis, pneumonia, pleurisy, a perforated ulcer, or appendicitis. Indeed in one of the patients, a man aged 26, laparotomy was performed; it revealed nothing amiss in the peritoneal cavity. In several cases relapses were observed either on the same or on the opposite side. Discussing the aetiology, the author draws attention to the likeness of this epidemic to those of epidemic myalgia or Bornholm disease. What was remarkable was the invariable limitation of the symptoms to the areas supplied by the phrenic nerve.

#### 545 Active Diphtheria Immunization

W REINHARDT (*Dtsch med Wschr* April 8, 1938, p 535) reports from a children's hospital in Lubeck certain observations indicative of the inability of active immunization to protect against diphtheria in many cases. In a convalescent home housing on an average 110 children, as many as sixteen cases of diphtheria occurred although the children had been actively immunized at a time when there was no epidemic of diphtheria. All the children had been examined for diphtheria bacilli in the nose and throat before being admitted to this home, and the bacteriological reports had been consistently negative. The children had in fact been artificially immunized against diphtheria under the best conditions. The shortest interval between immunization and the outbreak of the disease was one of seventeen days, and in four cases this

interval was longer than three months. The behaviour of the diphtheria in these sixteen cases was what might be expected in children not immunized, the disease ran a light course in four cases, a moderately severe course in ten cases, and a severe course in two. In a footnote to his article the author states that twelve further cases of diphtheria have recently broken out in the same convalescent home among children who had been artificially immunized, the interval between immunization and the outbreak of the disease had ranged from one to three months in most cases, but had twice been less than twenty days and had once been almost nine months. The author contrasts these observations with the claims made on behalf of active diphtheria immunization that the immunity it confers begins in four to five weeks and lasts several years. The principle of such immunization is not challenged by him, but he does insist that there is evidently room for improvement in the technique.

#### 546 Pneumothorax in Bullous Emphysema

K BUHLER (*Z Tuberk* March, 1938, p 300) gives an account of the occurrence of spontaneous pneumothorax in a case of congenital bullous emphysema. The patient was a man of 51, who first complained of slight shortness of breath on going upstairs in 1931. X-ray examination showed nothing abnormal apart from a widened aorta. In August, 1936, his family doctor diagnosed "hypertonia and a low-grade emphysema of both lungs," and sent him to a watering place for heart disease. On his second day there he suddenly complained of dyspnoea, which was diagnosed as being due to a spontaneous pneumothorax. This was confirmed by x-rays, and the patient returned to Berlin. Since the valvular pneumothorax showed no signs of closing up and no retracted lung tissue was to be seen, thoracoscopy was performed. This showed a complete right-sided pneumothorax, but the upper and middle lobes were not recognizable as lung tissue and presented the appearance of distended soap bubbles, in one of them a small hole was to be seen, covered by a membrane which moved on respiration. Olive oil was applied to the valvular opening with a view to causing slight local inflammation sufficient to seal the opening. This would seem to have been completely successful, for the patient ceased to suffer from dyspnoea, thoracoscopy eight days later revealed a plug of fibrin sealing the aperture, and a radiograph showed that the lower lobe had re-expanded.

#### 547 Latent Benzolism

P-E WEIL, PERLES and A ASCHKENASY (*Sang*, 1938, 12, 2, 151) give a long account, with elaborate statistical tables, of their investigations of latent benzolism. Fifty-four cases were examined, including thirty-three men, seventeen women, and four children. They were all, so far as appearances went, in good health at the time of examination. The authors comment on the frequency of benzolism in apparently healthy workers. It shows itself by a slightly hyperchromic anaemia, with neutropenia (chiefly in women) or eosinophilia (chiefly in men) and thrombopenia. The anaemia would seem to be hypoplastic from the start, for the bone marrow is frequently affected in these cases, though of course to a lesser degree and later than the circulating blood. In none of the cases was there any sign of an irritant effect of benzol, such as a tendency to polycythaemia or leukaemia as observed in experimental benzol poisoning. Gastric disturbances particularly achlorhydria or hypochlorhydria, are an early accompaniment of these blood signs. The authors recommend better workroom conditions, especially as regards ventilation, shorter hours of work, the establishment of special dispensaries where the workers would have to undergo compulsory medical examinations at stated periods, and the appointment of visiting inspectors to see that the above regulations were being properly observed.

## 548 Epidemic of Streptococcal Infections

L. KJELSTRUP (*Nord med. Tidskr.* March 5 1938 p. 801) gives an account of an epidemic of scarlet fever in Greenland associated with various streptococcal infections, the manifestations of which were polymorphous. Among the 422 cases from all causes in the district during 1935 and 1936 there were as many as 250 traced to scarlet fever or some streptococcal infection of the face, lungs, pericardium or peritonium. The deaths from scarlet fever itself which ran a comparatively mild course numbered only nineteen whereas there were seven from erysipelas, 120 from pneumonia and empyema of the pleura or pericardium and twenty from peritonitis other than that due to purpuril infections. As the population of the district was only 3701 at the end of 1936 the total death rate during the two years was about 11 per cent, at least 6 per cent being due to streptococcal infections. It was remarkable that while the death rate from scarlet fever was only 2 per cent, that from erysipelas was between 20 and 25 per cent.

## Surgery

## 549 Thrombectomy

D. KULENKAIEFF (*Disch. med. Wschr.* April 22 1938 p. 593) claims to have succeeded in several cases in preventing serious or even fatal pulmonary embolism by the operative removal of thrombi from the iliac veins. He considers thrombi formed in the external and internal iliac veins as most often responsible for pulmonary embolism. In four cases he has succeeded in extracting from the iliac vein clots lying free in the lumen of the vein, except at the point of attachment thereto. Under local anaesthesia he makes a 3 cm. long transverse incision just below Poupart's ligament. The vein is exposed, clamped in two places and divided. The peripheral end having been ligatured after noting whether blood escapes from it or not, the central end is freed from its small tributary vessels and is slit open. The thrombus when found is carefully detached and extracted. Only when plenty of dark blood flows freely out of the stump of the vein is it safe to assume that all the thrombus has been removed. In addition to the four cases already mentioned he refers to eleven others in which a thrombus without any stalk projecting into the vein was revealed by this operation.

## 550 Thrombosis and Embolism after Herniotomy

H. F. HARBITZ (*Norsk. Mag. Lægevidensk.* March 1938 p. 287) has studied 1046 cases of hernia operated on in the period 1926 to 1935 at the Ullevaal Hospital in Oslo. In 210 of these cases the patients' ages were under 20. The risks of thrombosis and embolism being small under this age, the study was limited to the remaining 836 patients. Operation was performed as a rule under local anaesthesia. A record of stabbing pain in the chest usually associated with a rise of the temperature and pulse rate was assumed to indicate embolism. Among the 550 patients operated on for inguinal hernia were fourteen cases of embolism and one death. There were five cases of embolism among the forty-seven patients operated on for femoral hernia but no deaths. There was only one case of embolism among the 108 cases of abdominal hernia of various kinds and in this group the only post-operative death was due to pneumonia. In all the above-mentioned three groups the hernias were not incarcerated. The frequency of thrombosis or embolism for all these non-incarcerated hernias was 2.8 per cent and the mortality from this cause only 0.14 per cent. Among 131 cases of incarcerated hernia (inguinal, femoral, etc.) there were four cases of embolism—a morbidity rate of 3 per cent and a mortality rate of 0.77 per cent. The frequency of this complication for all the patients over 20 was

2.87 per cent. Neither the sex of the patient nor the side of the body on which the operation was performed seemed to affect the rate. The author concludes that femoral hernias are more likely to be associated with thrombosis or embolism than either of the other two groups and this seems to be true both for the incarcerated and the non-incarcerated herniae.

## 551 Malignant Tumours of the Small Intestine

D. A. NICKERSON and R. H. WILLIAMS (*Amer. J. Path.* January 1938 p. 53) present a study of ten cases of malignant tumour of the small intestine. The cases are taken from 11206 necropsies performed from 1893 to 1935. Of these ten cases two were sarcomata, eight carcinomata, and as in these necropsies 243 cases of carcinoma of the gastro-intestinal tract were found in all the incidence of small intestine tumour was 2.33 per cent of the total incidence of alimentary carcinomata. Eight tumours took origin from the duodenum, two arose from the jejunum. The average age of the patients agreed with that for malignancy elsewhere (57 years), the youngest patient being aged 30, the oldest 72. Both sexes were attacked equally. Histologically the sarcomata were leiomyosarcomata while the other growths were all adenocarcinomata, six of which were polypoid and stenosing in type, two annular and constricting. In seven cases metastasis was late and followed the lymphatic drainage to the liver and to the mesenteric and retroperitoneal lymph nodes. The clinical picture varied according to the site of the tumour. In the paralytic there was obstruction with profuse vomiting and dehydration; in the peri-ampullary there was jaundice and in the pre-jejunal and jejunal types there was recurrent nausea, abdominal cramps and visible peristalsis. In four cases x-ray examination showed distortion of the duodenal cap.

## Therapeutics

## 552 X-Ray Therapy of Prostatic Hypertrophy

J. KNEIP (*Disch. med. Wschr.* March 11 1938 p. 377) reports from a surgical hospital in Worms his experiences with the x-ray treatment of hypertrophy of the prostate. Since 1930 the candidates for x-ray treatment have been those patients who for some reason or other had been considered as unsuitable for operation. In spite of this selection the author can claim a high proportion of cures and improvements in his series of thirty-seven cases. In sixteen the results were so good that the could be classed as recoveries; in twelve other cases some improvement could be claimed. Two patients had subsequently died of unknown causes and four of sequelae to the hypertrophy of the prostate. In three cases prostatectomy was performed after x-ray treatment had failed. In no case did the treatment do harm and the author concludes that provided the new growth in the prostate is benign, vasectomy followed by x-ray therapy is to be recommended particularly for those cases for which an operation is undesirable.

## 553 Sulphanilamide Treatment of Meningococcal Meningitis

A. ELDAHL (*Ugeskr. Laeg.* April 7 1938 p. 365) has administered streptamid—a Danish sulphanilamide preparation—to twelve consecutive cases of meningococcal meningitis treated at a fever hospital in Denmark. From 5 to 30 ccm of a 0.8 per cent solution were given daily by intrathecal injection. At the same time from 35 to 120 ccm of the same solution were given daily intramuscularly. This treatment was supplemented for the first ten to twenty days by the daily withdrawal of cerebrospinal fluid, the amount withdrawn being always a little more than the amount of solution to be injected. Later these withdrawals of cerebrospinal fluid were undertaken every two to three days. The oldest patient was—

aged 4, and seven were less than 1 year old. Though all the cases were severe, there were only three deaths, one of which was doubtless hastened by double acute suppurative otitis media, present on admission to hospital and by pneumonia. In another of the three fatal cases the general condition of the child had been very unsatisfactory before the meningitis developed, and the percentage of haemoglobin had been only 45. During the past six years the mortality at the author's hospital among sixty-eight children under 4 years, suffering from meningococcal meningitis, has been about 70 per cent. The author notes that in his own and in the experience of others, meningococcal meningitis is apt to prove refractory to sulphanilamide preparations if they are given only by the mouth or by intramuscular injection. But if, at the same time, the latter mode of administration is supplemented by the intrathecal administration of this drug, the results are remarkably good.

#### 554 Vitamin B for Alcoholic Polyneuritis

R. GOODHART and N. JOLLIFFE (*J. Amer. med. Ass.*, February 5, 1938, p. 414) discuss the results of treating with large amounts of vitamin B seventeen mild uncomplicated cases of alcoholic polyneuritis of short duration. All were given by mouth four times their normal requirement of vitamin B and alternate cases (eight of the seventeen) were given intravenously in addition 10 mg. of crystalline vitamin B daily for ten days, thus increasing the vitamin intake to sixteen times their normal requirement. By every method of comparison the response of those cases receiving the crystalline supplement was better and quicker than that of the other nine. The authors conclude that vitamin B deficiency is the primary cause of alcoholic polyneuritis, and that improvement in the objective signs of the disease varies directly with the vitamin B intake.

#### 555 Radium Therapy of Benign Skin Conditions

A. MUSGER (*Wien klin. Wschr.*, March 4, 1938, p. 274) points out that radium is of value in the treatment of certain benign skin conditions. The soft alpha rays may be used in the treatment of herpes zoster, neurodermatitis, forms of dermatitis due to salvarsan, and in pruritus, the rheumatoid dermatoses, and psoriasis. The hard beta and gamma rays should never be used when there is evidence of former damage by irradiation to the skin—for example, telangiectases, atrophy, and pigmentary changes. Treatment should be discontinued when evidence of increased sensitivity to irradiation is present. Radium therapy is the method of choice in the treatment of cavernous haemangiomas, spontaneous keloids and hypertrophy of scar tissue, syphilis, and plastic induration of the penis. Certain conditions react better to radium than to other forms of treatment. They include plantar warts, anal eczema, chronic inflammations of the nail fold and behind the ear, circumscribed pruritus, and various forms of tuberculosis of the skin and mucous membrane.

## Neurology

#### 556 Manganese Chloride in Tuberculous Meningitis

V. GORLITZER (*Med. Klinik*, March 11, 1938, p. 334) describes a new treatment of tuberculous meningitis with manganese chloride. The substance used is  $MnCl_2 \cdot 4H_2O$  in 0.2 molar solution, prepared under the trade name of "metalloid", 1 to 2 ccm. are given rectally twice daily for one to two weeks. 1 ccm. may also be given by intrathecal injection, intravenous injections are not well tolerated. Seven cases are reported, in six of which the treatment led to recovery, in the one case in which it was not effective the patient had generalized military tuberculosis. The values for the chlorides and sugar in the cerebrospinal fluid are not given, but in one case with recovery

acid- and alcohol-fast bacilli were found in this fluid. The author considers that the drug leads to a stimulation of the formation of antibodies, either in the gut during absorption or in the meninges, and does not act directly on the bacillus. He also considers it possible that serous lymphocytic meningitis is a benign form of tuberculous meningitis, and in such cases the effect of manganese chloride is dramatic.

#### 557

#### Delirium Tremens

P. PIKER (*Arch. Neurol. Psychiat.*, Chicago, January, 1938, p. 62) discusses the use of fluids in the treatment of delirium tremens. A series of three hundred cases were divided into two equal groups and similar treatment carried out in each, except that in one group the fluid intake was limited to 1,000 ccm. and in the other fluids were forced to between 3,000 and 4,000 ccm. in the twenty-four hours. No striking difference was observed between the two groups, but a larger number of cases with severe symptoms were found amongst those having forced fluids. Also in this group more cerebrospinal fluid could be drawn off at subsequent lumbar punctures than in the group with restricted fluids. The author points out that owing to other details of the treatment—namely, the administration of hypertonic glucose intravenously—it is impossible to say definitely that the forced fluids led to increase of the cerebral oedema which is present in this condition. There seems, however, little value in restricting fluids unnecessarily; and it is concluded that the patient should be given as much fluid as he desires for comfort, and dehydrants and spinal drainage used as may be indicated by the course of the condition.

#### 558

#### Multiple Sclerosis

G. SCHALTENBRAND (*Med. Welt*, March 26, 1938, p. 435), in discussing the theories of causation of multiple sclerosis, states that the oldest, which held that the condition was hereditary, is again receiving attention. The theory that it is due to a diffusion of a ferment from the blood stream or ventricles into the cord substance has not yet been entirely disproved. Infection has been demonstrated by animal experiment to be an aetiological factor, but no proof has been adduced that multiple sclerosis is a meta-tuberculous disease. The resemblance between sclerosis and funicular myelosis has been pointed out, for in both the blood and bone marrow are affected. In the former, however, the diameter of the erythrocytes is normal. A history of avitaminosis or of accident was obtained in a number of patients. Lead poisoning has been known to produce the disease. Thrombus formation in the cerebral veins is believed to be a causative factor. The author believes multiple sclerosis to be a non-specific neuro-ectodermal reaction.

#### 559

#### Phlegmonous Encephalitis

H. BRUNNER and R. DINOLT (*Z. ges. Neurol. Psychiat.*, 1938, 162, 1 and 2, 107) describe two cases of otogenic purulent progressive encephalitis, a clinical picture which they consider is sometimes obscured under the term 'cerebral abscess'. In the first case a man aged 44, following a right mastoid operation, developed a high temperature, drowsiness, early papilloedema, hemianopia to the left and slight left-sided pyramidal signs, with a high leucocytosis in the blood and an increase of cells and protein in the cerebrospinal fluid. A further operation revealed lateral sinus thrombosis and haemorrhagic and necrotic brain tissue from the occipital lobe protruded into the wound. Death took place fourteen days after the first operation. Necropsy revealed suppurative and haemorrhagic encephalitis throughout the right occipital lobe involving the posterior horn of the ventricle and extending into the corpus callosum. Microscopically thrombosis of vessels, foci of softening infiltrated with leucocytes and streptococci and diffuse suppurative foci were found. The second case was similar, the duration of the illness

after the first operation being twenty-three days. The author regards the condition as a phlegmonous encephalitis distinct from both acute and chronic cerebral abscess. The pathology of cerebral abscess is discussed. Infection which reaches the white matter along the veins first gives rise to a circumscribed focus of purulent encephalitis. This may develop in three different ways and give rise to a chronic abscess, an acute abscess, or a phlegmonous encephalitis. These conditions are all variations of the same pathological process but they merit clinical differentiation.

## 560 Hypertensive Apoplexy

W. H. CHASE (*Arch Neurol Psychiat*, Chicago, December 1937, p. 1176) discusses hypertensive apoplexy and its causation. He made a general clinical and anatomical analysis of eighteen cases of pure uncomplicated hypertension which were found in a series of 105 cases of haemorrhage of the brain. Fifteen of these were cases of essential hypertension without arteriosclerosis and three were cases of hypertension associated with atherosclerosis. Anatomically in the first group he found thickening of the intracranial arteries and haemorrhages varying in size, number, position and age. The larger haemorrhages, over 2 cm. in diameter, consisted of laminated fibre and blood cells and the clot also contained many fine stiff irregular vessels. Multiple minute haemorrhages were found especially in the corpus striatum of the thalamus and pons and perivascular clots, either nodular or encircling the vessel and intimately related to the adventitia, also occurred. Capillary thrombi were numerous but thrombi in the large arteries and veins were not. The view expressed is that the long continued constrictor irritation leads to fatigue and dilatation of the capillaries and arterioles, while the proximal arteries may still be constricted. This parastaltic hyperaemia leads to increased permeability of the dilated vessel walls possibly because of the poor oxygen content of the blood with which their walls are nourished and diapedesis follows although there is no interruption of blood flow beyond the point of diapedesis. If blood movement ceases thrombosis and infarction follow. The intimate perivascular haemorrhages are possibly due to a proximal spread of the vascular spasm and involvement of the vasa vasorum. There is no rupture of the artery wall. In transient hypertension the only changes are petechial haemorrhages from terminal capillaries and arterioles, the causation of which is probably similar.

## 561 Surgery of Trigeminal Neuralgia

A. SNELLMAN (*Nord med Tidskr*, March 19 1938, p. 457) has observed in his hospital in Finland in the course of the past year twenty cases of genuine trigeminal neuralgia, nineteen of which he has treated by electrocoagulation of the Gasserian ganglion according to the technique introduced by Kirschner in 1933. In fifteen cases a single treatment was sufficient to achieve freedom from symptoms and in three cases from two to four treatments were necessary to obtain complete relief. In one case the needle could not pass through the foramen ovale on account of the calcification induced by earlier injections of alcohol. There was also a case which had been treated without effect by electrocoagulation at another hospital; it yielded to antisyphilitic treatment. Among the complications following electrocoagulation was neuroparalytic keratitis, one case, of which was observed eight months after the operation. The author's opinion of this treatment is on the whole favourable and he notes that the complications to which it gives rise are practically identical with those associated with other methods of treatment. The sensory disturbances are as a rule trifling, and involvement of the cornea ought to be avoided by perfecting the technique. This opinion implies keeping the operation in the hands of those who have

specialized in it the necessary technical finesse requiring considerable skill and practice. The author believes that electrocoagulation of the Gasserian ganglion should completely oust peripheral alcohol injections and should at any rate rank as equal with central alcohol injections but it cannot be expected to displace Danov's suboccipital operation.

562 P. WERTHEIMER and G. MIMOUN (*J. Med. Lyon*, March 1938, p. 151) review the late results of retro-Gasserian nerve section by the temporal route. In a series of seventy-eight operations there were two operative deaths which occurred in the first ten cases. Fifty-six of the patients were observed for periods varying between eight months and thirteen years. Eight patients were found to be suffering from recurrence of the pain. Such an event may be due to an incomplete or incorrectly placed section, five patients belonging to this group were completely cured after a second operation. Failure may also be due to operation being performed on unsuitable cases. In five patients the appearance of an ill defined, continuous pain was noted associated with vasomotor and secretory disorders. This was a temporary phenomenon. A third group of patients complained of paraesthetic sensations of a painful nature and localized to a very small area. In 5 per cent of cases neuralgic pain appeared on the opposite side of the face. The post operative anaesthesia was found to be temporary. The corneal reflex was present four months after operation, four years after operation sensation in the area affected was practically normal. Ocular complications were seen in 9 per cent of all cases, only two of these patients are left with permanent corneal scars. Severe neuroparalytic keratitis was not seen. The suggestion is made that post operative paralysis of the oculomotor and facial nerves may be due to a vasomotor disturbance of the vasa nervorum and the authors propose to verify this explanation when next they find a suitable case. Infiltration of the superior cervical or the stellate ganglion should throw some light on this problem.

## Obstetrics and Gynaecology

### 563 Blood Changes in Cancer of the Uterus

P. JACOBY and J. SPOTOFT (*Hospitalstidende*, March 15 1938, p. 274) have investigated in ninety-one cases the influence of cancer of the uterus on the sedimentation rate. Before treatment was instituted this rate was normal in forty-four cases and above normal in the remainder. The further advanced the disease the higher was the proportion of sedimentation rates above normal. Comparing these findings with those of other observers the authors note that their own records show a relatively high proportion of cases with a normal sedimentation rate. Among the thirty-three cases in which the sedimentation rate was measured before and after treatment with radium there were twenty-two in which this rate was increased whereas in the remaining eleven cases it showed a decrease. So far as these observations were concerned the behaviour of the sedimentation rate during treatment would seem to be of little prognostic value. With regard to the significance of the sedimentation rate after the completion of treatment the authors note that as in cancer of the breast a persistently high rate of sedimentation is a sign of ill omen whereas a consistently low or normal rate is of good prognosis.

564 J. NEUKA (*Wien klin Wschr*, April 8 1938, p. 405) has investigated the blood picture and the blood sedimentation rate in twenty-five cases of carcinoma treated with deep x-ray therapy. There were twenty-two cases of carcinoma of the cervix, two of carcinoma of the body of the uterus, and one of carcinoma of the

ovary The white cell picture before the irradiation showed no typical changes In almost one-half of the cases the white cell count was normal, while in the remaining cases the number of leucocytes was increased up to 18,000 per cmm During the course of treatment the leucocyte count dropped to one-half or even to one-third in 92 per cent of cases returning to its original figure after three months The application of 4,000 r in fractional doses distributed over ten sittings in ten days had no injurious effect on the white blood cells The sedimentation rate may be increased in cases of uterine or ovarian carcinoma, a further increase may occur during the course of x-ray treatment The authors conclude that the blood picture and the blood sedimentation rate are of no diagnostic or prognostic significance in cases of uterine or ovarian carcinoma

### 565 Novocain Infiltration of the Pelvic Sympathetic

J HENRIET (*Rev franç Gynec* March 1938, p 139) alludes to recent modifications of current views concerning the anatomy and physiology of the pelvic autonomic nerves in the human subject, and to the evidence—from Leriche's lumbar sympathectomy in Little's disease, Cottes's pelvic sympathectomy for vaginismus, and Reeb's finding of relaxation of the levator ani during labour in a woman in whom the presacral nerve had been resected—that striated as well as smooth muscles are susceptible to autonomic nerve control He records eighty-five obstetrical cases in which he has anaesthetized the pelvic peritoneal plexus, lying laterally to the upper third of the vagina and to the cervix In reaching the plexus access through the lateral fornices is rejected (as carrying, from practical difficulties in a sepsis, the danger of infecting the broad ligament) in favour of insertion of the long needle of the syringe in front of the posterior commissure, external to the labium majus The transit of the needle is controlled by two fingers in the vagina, the injection is made with 20 ccm of 1 per cent novocain, without adrenaline The object of the technique has in fifty-six cases concerned the perineum, in twenty-nine the cervix In the first group it was sought to diminish perineal resistance and prevent tears in four primiparae aged 38 to 43 thirty-one primiparae with vulval constriction, eleven multiparae who had previously had bad tears, and ten cases of abnormal presentation It was found that pain was diminished, passage of the head over the perineum accelerated and facilitated by the muscular relaxation, and the number of obstetrical interventions greatly reduced The second group comprised all cases of protracted first stage of labour from cervical rigidity, oedema, or scarring full dilatation speedily followed Antispasmodics were given at the same time, or small doses of pituitary extract, according to the state of the uterine contractions Obstetrical interventions were unnecessary in the series of twenty-nine cases

### 566 Age and Fertility

O KOLB (*Munch med Wschr* April 8, 1938, p 502) has reviewed 59,117 gynaecological and obstetrical cases from the point of view of fertility and age The fertile period stretched between the ages of 12 and 49, with an optimum at 23 The fertility of the group between the ages of 12 and 15 was only slight, but it rapidly increased from the age of 16 The gradual decrease of fertility after the age of 23, apart from natural causes seemed to be due to diseases resulting from previous childbearing, acquired sterility as a result of criminal abortion, the increase of venereal diseases, the increased use of contraceptives and the decrease in sexual intercourse with increasing age Since the war the difference between the habits of the urban and rural population has been levelled out The rural population too have become acquainted with contraceptives and criminal abortion Conditions have probably changed in those countries where a premium is put on fertility On the whole the survey

showed that fertility in a civilized country is influenced by a variety of factors, not the least of which are economic A true picture of the relationship between age and fertility could only be obtained in a primitive community uninfluenced by modern civilization and free of material cares

## Pathology

### 567 Intradermal Test for Trichinosis

W CALUS (*Acad des Sci de l'Ukraine* 1938 8 316) has investigated the diagnostic value of the reaction caused by injecting intradermally the specific antigen of the trichinella The special antigen prepared for the author by the Institute of Microbiology and Epidemiology was tested 331 times on sixty-six patients suffering from trichinosis The reaction was positive in 74 per cent of the cases, whereas of 104 normal control cases only 5 per cent showed a positive reaction In two cases of hydatid cyst of the liver reaction with the trichinella antigen was negative, while the reaction with the hydatid antigen was positive The reaction is independent of the gravity of the case, though in all the severe cases it was positive

### 568 Non-specificity of "Anti-cancer Serum"

H J PHELPS (*Am J Cancer* November, 1937, p 441) describes experiments undertaken to determine the effect of the sera of rats given repeated injections of Jensen rat sarcoma tissue on Jensen rat sarcoma cells The sera of three series of rats, immunized respectively with Jensen rat sarcoma tissue, emulsions of normal rat spleen and normal rat blood, were tested against cultures of Jensen rat sarcoma cells, normal rat spleen cells, mouse carcinoma 63 cells, and normal mouse spleen cells Sera from both sarcoma-immunized and spleen immunized rats were toxic to cultures of all four types Whole blood was a less effective antigen than the other two agents The author concludes that "anti-cancer sera" have no specific action on malignant cells and probably, therefore, cannot be therapeutically useful that the antigen in cancer cells evoking the antibodies studied is not peculiar to malignant cells, and that these antibodies are probably iso-antibodies formed in response to foreign though homologous cells

### 569 Sulphanilamide and the Pathogenic Anaerobes

R S SPRAY (*J Lab clin Med* 1938, 23 609) has studied the *in vitro* effect of sulphanilamide, disulphanilamide, and prontosil soluble on various spore bearing anaerobic bacilli especially those associated with gas gangrene A broth medium was prepared with 1 per cent tryptone, 1 per cent neo-peptone, and 0.2 per cent dextrose in distilled water Serial dilutions of the drugs were made in the broth tubes, which were covered with a heavy oil seal and autoclaved at 120° C for twenty minutes The tubes were cooled rapidly and inoculated with about 0.05 ccm of a twenty-four-hour-old culture in semi solid agar of the anaerobe to be tested All cultures were incubated at 37° C, and the degree of turbidity was used to measure the amount of growth that had occurred It was found that certain species, such as *Cl tetani*, *Cl oedematis*, *Cl septicus*, and *Cl histolyticum* were specially susceptible to the drugs used, while *Cl welchii* and the highly proteolytic types, such as *Cl sporoginus* and *Cl bifermentans* and including the toxic *Cl botulinum* Type A, were much less affected The bacteriostatic activity increased in the following order: prontosil soluble, sulphanilamide, disulphanilamide The last compound completely prevented growth of all the anaerobes tested in a dilution of 1 in 250 *Cl tetani* and *Cl histolyticum* were inhibited by a dilution of 1 in 1,000, *Cl oedematis* by one of 1 in 4,000, and *Cl septicus* by one of 1 in 8,000

## Pure, active, comfortable and inexpensive

An increasing tendency is shown to claim a very high purity and remarkable hæmopoietic potency for injectable fractions of liver

Independent chemical research in stringent conditions of clinical test has maintained the place of Organon's PERNAEMON FORTE in this field

PERNAEMON FORTE, now a clear solution provides a medium for the therapy of Pernicious Anæmia as pure as active as comfortable and as inexpensive as any available.

## Successful Vaccine Therapy in PUSTULAR ACNE

Prices 5 cc bottles 7/6 10  
10 g 25 cc 17/6 Less usual  
professional discount

**A NEW INJECTION TECHNIQUE**—Resistant cases of both primary and secondary acne infection have responded strikingly to continued intradermal and subcutaneous injection using the Acne Staphylococcus Dissolved Vaccine. Being already in solution, the antigens are released immediately into an area rich in reticulo-endothelial cells. Yet the injection is free from incapacitating reaction because detoxication is also a feature of the Dissolved Vaccine.

The method recommended for a 1 cc dose is to introduce 0.1 cc, 10 or 20 cc, into the skin continuing through to give the remainder subcutaneously. A fine needle should be used. One such injection each week for 8 to 12 weeks usually suffices to clear up even long-standing cases.

Immediate Antibody Response from

PARK ROYAL ROAD LONDON N W 10

## TOTAL VITAMIN B ACTION

Aluzyme supplies all the members of the Vitamin B Complex in a fully active state. The B Vitamins form a synergy the separate factors of which accentuate or facilitate the action of the others (*Med Research Council's Special Report 167*). In all B deficiency conditions the best results may be anticipated from administration of the entire Complex which Aluzyme provides B<sub>1</sub> potency 1140 Internat Units per ounce. Active response to tests for nicotinic acid, flavin, and glutathione.

# THROMBIN-COAGULANT-MAW DRESSINGS HAVE PROVED THEIR EFFICIENCY!

In the short time they have been on the market Maw's TCM Dressings have achieved remarkable success. Members of the profession who have used them have been impressed by the rapidity with which coagulation is achieved and numerous instances are recorded of severe haemorrhage being checked almost instantly. TCM Dressings are treated with Thrombin Coagulant Maw, a preparation of natural Thrombin which accelerates blood coagulation and causes clotting within 5-15 seconds. They are supplied sterile in sealed drums ready for immediate use and the series consists of special Lint Squares suitable for most purposes. Special TCM Dressings can be supplied when required.

They cost only a trifle more than ordinary Dressings and are well worth the extra charge. We ask you to give them a fair trial for we are confident that you will be satisfied with the results.

## UNIVERSITY OF LONDON KING'S COLLEGE FACULTY OF MEDICAL SCIENCE

The Medical Faculty at this College of the University gives instruction in the subjects of Medical Science for all the usual Pre medical and Intermediate Examinations in Medicine, Surgery and Dentistry. Through the four associated hospitals, students of the College have clinical facilities of over 1,000 beds.

The Medical Faculty of the College provides a general University education in touch with other faculties, classes of which medical students are permitted to attend. There are many College societies, clubs and functions in which students of all faculties have opportunity of meeting, each other. The College has an excellent athletic ground at Mitcham with a new and well equipped pavilion.

The First Year subjects are taught in the large Departments of the Faculty of Science, and those of the Second and Third Years in the new Medical Department. This includes the Hammersmith Department of Anatomy and an extension to the Department of Physiology recently completed at a cost of £10,000. These new buildings and those of recent years provide the College with a completely new and modern Medical Department which embodies the newest ideas in laboratory construction and equipment.

Valuable scholarships and prizes are awarded on the results of examinations held annually.

The Hostel for men students (The Platens, Champion Hill, S.E. 5) contains accommodation for 50 students. The Hostel for women students is at 55, Queensborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean of the Medical Faculty or to

S. I. SHOVELLON, M.A. Secretary

## COUNTY BOROUGH OF ROTHERHAM MEDICAL SERVICES COMMITTEE

### 1 ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from fully qualified Medical Practitioners with the necessary knowledge and experience of hospital work for the appointment of a full time Resident Assistant Medical Officer at the Alma Road Hospital, Rotherham at a salary of £350 per annum together with the usual emoluments. The appointment will be made for a period of twelve months.

Candidates must be medical practitioners of at least one year's standing and have held a resident appointment in general hospital or municipal hospital for at least six months.

### 2 JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER

Applications are also invited for the post of Junior Assistant Resident Medical Officer at the Alma Road Hospital, Rotherham at a salary of £180 per annum together with the usual emoluments. The appointment will be for a period not exceeding twelve months determinable by one month's notice on either side.

The above appointments are subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the successful candidates will be required to pass a medical examination.

The persons appointed will be required to act under the general direction of the Medical Superintendent.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Rotherham and must be returned to the undersigned endorsed with the title of the appointment not later than noon on June 30th 1938.

Municipal Offices CHAS. L. DES FORCES  
Rotherham Town Clerk

## COUNTY BOROUGH OF SUNDERLAND

### APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified medical practitioners for appointment as an Assistant Medical Officer of Health and Assistant School Medical Officer. Applicants should have had at least three years' experience of the practice of medicine since qualification and the possession of a Diploma in Public Health will be considered advantageous.

The successful candidate will work under the supervision of the Medical Officer of Health. The work will include Medical Inspection of School Children, Maternity (Ante Natal) and Child Welfare work and such other duties as may be allotted.

The candidate appointed will be required to devote his or her whole time to the duties of the position and will not be allowed to engage in private practice.

The salary will be at the rate of £500 per annum advancing by annual increments of £25 to a maximum of £700 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the selected candidate will be required to pass a medical examination.

Applications addressed to me and endorsed on cover Assistant Medical Officer must be delivered at my office not later than Saturday July 2nd next.

Conveying either directly or indirectly before the first selection of candidates by the Committee will be a disqualification.

Town Hall G. S. MCINTIRE  
Sunderland Town Clerk  
June 11th 1938

## CITY OF SHEFFIELD NEITHER EDGE HOSPITAL

Applications are invited from duly qualified medical women for the appointment of ASSISTANT MEDICAL OFFICER at the above hospital.

The Medical Officer appointed will be required to reside in the hospital and assist in the medical and maternity sections. She will also take part in the Maternity and Child Welfare work of the Corporation, taking Ante Natal Post Natal or Child Welfare Clinics daily at the Maternity and Child Welfare Centre.

Candidates should have previous hospital experience and postgraduate experience in Midwifery and Ante Natal work is essential.

The salary offered is £350 per annum rising by £25 to £450 with the usual residential allowances. The appointment will be subject to the provision of the Local Government and Other Officers Superannuation Act 1922 and deductions will be made under this Act.

Applications stating age, qualifications and experience accompanied by three recent testimonials should be sent to the Medical Superintendent, City General Hospital, Sheffield S.1 on or before July 6th 1938.

# INDIAN MEDICAL SERVICE

## RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years service or of £2,500 after 12 years service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 27 years of age and who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

### CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General. An officer may apply at any one year's Indian Service to have his name considered for transfer to the civil side from which appointments are made to Civil Surgeons, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes, to specialist (for example, public health and bacteriological) services, to research posts and to professorships at the Medical Schools.

### RATES OF PAY

24	"	1300	15	1695
25	"	1500	15	1815
26	"	1500	15	1815

Note—(1) The rupee is at present stabilized at a rate equivalent to 1s 6d.  
(2) An officer promoted to the rank of Lieut. Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1,500 per mensem (basic) plus £10 per month overseas pay.

Extra—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

### ANTEDATEDS IN COMMISSION

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized

hospitals may be seconded in those posts for a period. The maximum period of antedate secondment, or antedate and secondment combined admissible under this paragraph is limited to 18 months.

### OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

### PRIVATE PRACTICE.

With the exception of Administrative Officers military or civil and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

### LEAVE.

Leave can be taken at reasonable intervals and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed twelve months in all during an officer's service may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave study allowance at present fixed at the rate of 12s a day in the United Kingdom, £1 a day on the Continent of Europe and £1 10s a day in the United States of America and Canada is granted to an officer in addition to ordinary rates of leave pay.

### PENSIONS

The rates of pensions are as follows — Per annum.

After 17 years' service for pension	Per annum.
" 18 " " "	£572 0s.
" 19 " " "	£400 0s.
" 20 " " "	£428 0s.
" 21 " " "	£463 0s.
" 22 " " "	£502 0s.
" 23 " " "	£539 10s.
" 24 " " "	£576 10s.
" 25 " " "	£614 0s.
" 26 " " "	£651 0s.
" 27 " " "	£697 10s.
" 28 " " "	£744 0s.

There are additional pensions ranging from £65 to £300 per annum for officers who have held administrative appointments.

### PASSAGES

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

### INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. The Selection Committee will meet at the India Office about July 26th next and the selected candidates unless seconded for hospital appointments will be required to join a course of instruction commencing about September 1st prior to sailing for India in December 1938. Applications should reach the India Office as soon as possible.

INDIA OFFICE, JUNE, 1938

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in September, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post-graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st August, 1938.

## ROYAL NAVAL DENTAL SERVICE

Applications are invited for appointment to commissions as DENTAL OFFICERS in the ROYAL NAVY.

Candidates who must be British subjects below the age of 28 years must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dentists Acts or Medical Acts. Unmarried candidates are preferred. No examination in professional subjects will be held, but candidates will be required to attend at the Admiralty for interview and for physical examination as to their fitness for service in any part of the world.

Successful candidates will be appointed to short service commissions as Surgeon Lieutenants (D) and will receive a grant of £50 towards the cost of providing the necessary uniform on entry. Vacancies in the permanent list will be filled by selection from among officers holding short service commissions who desire to make the Royal Naval Dental Service their permanent career. Officers not transferred to the Permanent List will on the termination of their short service engagement after six years' service receive a gratuity of £1,000.

Opportunities are available for officers on the permanent list for post-graduate study. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Naval Dental Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Application Forms and copies of the regulations for entry and conditions of service rates of pay and allowances etc. may be obtained from the Medical Director-General of the Navy, Admiralty, S W 1 and from the Deans of Dental Schools.

## SUDAN MEDICAL SERVICE

Applications are invited for the post of JUNIOR BRITISH LABORATORY ASSISTANT male unmarried in the Stack Medical Research Laboratories, Khartoum to commence duty on November 15th 1938.

The salary commences at ££324 or ££360 (££ = £1 0s 6d) according to age and qualification rising by two-three yearly increments to ££750 after eighteen or twenty years depending on the initial rate. The appointment carries prospects of pensionable service after five years' service. A free passage to the Sudan will be provided.

Candidates should be between 21 and 30 years of age and should hold the Laboratory Assistant's Diploma of Bacteriological Technique and preferably have some experience in Clinical pathology. Application stating age, qualifications and copies of testimonials should be sent to Dr H. C. Scalets, 93 Hurler Street, W. 1.

## THE ARMY DENTAL CORPS

Applications are invited from DENTAL SURGEONS for appointment to a limited number of COMMISSIONS in the Army Dental Corps.

Candidates who should not be over 28 years of age will for the present be selected for commissions without competitive examination but will be required to present themselves in London for interview and physical examination. They must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dentists Acts or Medical Acts.

Successful candidates will in the first instance be given short service commissions for six years at the end of which period they will retire with a gratuity of £1,000 unless they have been granted permanent commissions. Permanent commissions will be given to officers selected from among those who wish to make the Army their permanent career.

Particulars including Regulations for Admission pay and allowances and forms of application may be obtained on request either in writing or in person to the Director Army Dental Service, The War Office, London S W 1.

## BURY AND DISTRICT JOINT HOSPITAL BOARD

### RESIDENT ASSISTANT TO THE MEDICAL SUPERINTENDENT

Wanted an ASSISTANT TO THE MEDICAL SUPERINTENDENT of the Institutions of the Joint Board. These consist of a Fever Hospital (100 Beds), a Sanatorium (70 Beds) and a Small pox Hospital. Candidates must be registered Medical Practitioners. The appointment is a whole time one and the person appointed will asist the Medical Superintendent generally and as he requires. Preference will be given to candidates with hospital experience and special experience in Pulmonary Tuberculosis.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922.

Commencing salary £400 per annum with £25 increase at the end of the first year and a further £25 increase at the end of the second year with board washing and lodging.

Applications stating age, qualifications and experience together with testimonials to be sent to me on or before June 30th.

Hornby Building, The Rock Bury, Lancashire. F. A. BRADLEY, Clerk to the Board.

## CITY OF COVENTRY

### ASSISTANT SCHOOL MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH

The Coventry City Council invite applications from registered medical practitioners under 40 years of age for the post of Assistant School Medical Officer (male) in connection with the medical inspection etc. of school children. When not engaged in school work the officer will be required to assist in the general work of the Public Health Department.

Applicants must possess a Diploma in Public Health and preference will be given to those with appropriate previous experience.

The salary will be £500 rising by annual increments of £25 to a maximum of £700 per annum.

The post is designated under the Local Government and Other Officers Superannuation Act 1922 as amended in regard to annuities to widows by the Coventry Corporation Act 1936 and the successful applicant will be required to pass a medical examination as to fitness and to contribute to the superannuation fund. The successful applicant will also be required to contribute to the Coventry Staff Widows and Orphans Pension Fund.

Applications together with copies of three recent testimonials must be made on the prescribed form (which may be obtained from the undersigned) and must be delivered not later than June 9th 1938.

FREDERICK SMITH, Town Clerk.

The Council House, Coventry, June 14th 1938.

## CITY OF BIRMINGHAM

### DUDLEY ROAD HOSPITAL (926 Beds)

Applications are invited from fully qualified Medical Practitioners for whole time appointment as JUNIOR MEDICAL OFFICER (male) at the Dudley Road Hospital Birmingham. The appointment will be for a period of six months but may be extended for a further period of not exceeding six months. Salary at the rate of £400 per annum and full residential emoluments.

Further particulars may be obtained from the Medical Superintendent at Dudley Road Hospital to whom applications stating age, experience and qualifications with copies of recent testimonials should be forwarded not later than Thursday July 7th 1938.

## COUNTY COUNCIL OF MIDDLESEX

### RESIDENT ASSISTANT MEDICAL OFFICER (SURGICAL)

#### WEST MIDDLESEX COUNTY HOSPITAL. Twickenham Road Islington

Applications are invited from registered Medical Practitioners for the above appointment.  
Candidates must have held recent appointments at a general hospital and have had special experience in surgery.

Salary £500 per annum rising by annual increments of £25 to £475 per annum with board house and laundry.

The appointment which is subject to medical exam at but does not at present carry any superannuation rights will be held during the pleasure of the Council and is for a period of five years. At the end of this period the officer will leave the Council's service. In special cases the Council may desire to retain an officer on the established staff in which case the salary will be increased to a maximum of £500 per annum. The appointment is terminable by one month's notice on either side.

The officer appointed will work under the control of the Medical Superintendent and will devote his whole time to official duties.

Applicants stating age, qualifications and experience to either with copies of not more than three recent testimonials must be received by the undersigned not later than July 2nd, 1935. Relationship to any member or officer of the Council must be disclosed in the application. Envelopes must be endorsed "Resident Assistant Medical Officer West Middlesex County Hospital".

Canvassing directly or indirectly will be a disqualification.

C. W. RADCLIFFE, "Z"

Clerk of the County Council

Middlesex Guildhall  
Westminster S.W.1  
June 13th 1935

## COUNTY COUNCIL OF MIDDLESEX

### ASSISTANT MEDICAL OFFICER

Applications are invited for the appointment to the post of an Assistant Medical Officer in the Public Health and School Medical Department. Salary £600 per annum rising after two years service by annual increments of £10 to £620 to coincide with out-of-pocket allowances.

Candidates must be duly qualified registered medical practitioners and should have had special experience in public health work. The position of a doctor or diploma in Public Health will be an essential qualification.

The duties of the post are in medical inspection of school children the supervision of treatment of notifiable diseases and the care of women under the Maternity and Child Welfare Scheme and such other duties as may be required by the Council. The officer appointed will devote whole time to the duties of the post and under the direction of the County Medical Officer of Health and will be subject to medical examination which will be held during the pleasure of the Council and will be terminable by one month's notice on either side.

Applicants stating age, qualifications and experience together with copies of not more than three recent testimonials must be received by the undersigned not later than July 2nd. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. The Agency has made arrangements for special facilities on very favourable terms to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

sick children.  
Babies who do not thrive.  
Convalescents.  
Dyspeptics.  
Expectant mothers.  
Nursing mothers.  
Hypoaethenics.  
And the patient who  
is always below par.

---

All these and many more have been greatly benefited by a course of Numol and more than 6,000 of them have written to tell us

Numol is available for all patients, and the expensive character of its production need not prevent even the poorest person having the benefit of its help as free and specially reduced-price supplies are placed at the disposal of doctors for those who cannot otherwise afford to get it

Doctors are invited to write for a booklet containing a large amount of clinical data
